"MY THANKS TO OLIVER FOR ENSURING WE MEET
THIS BOARD'S QUOTA OF WOMEN."

Low-frequency radio continuum in optically selected quasars

Gulay Gurkan Uygun | OCE Postdoctoral fellow

Energetics and life-cycles of radio sources, March, 2018

CSIRO ASTRONOMY AND SPACE SCIENCE

www.csiro.au

Outline

- Motivation

- Quasar sample and radio data

 - SDSS QSOs

 - LOFAR data over the HETDEX and H-ATLAS/NGP regions

- Results

 - Radio loudness (\mathcal{R}) as a function of redshift (z),

 - spectral index (α),

 - black hole mass (M_{BH}),

 - Eddington ratio (λ_{Edd})

- Future work and conclusions

Motivation

- *Is there a radio loudness dichotomy in QSOs?*
- *Does \mathcal{R} depend on any SMBH parameters?*
- *What is the source of radio emission in optically selected QSOs?*

The classification ratios defined to date are not clear

The definition of radio loudness involved using fluxes (or luminosities) at a various optical and radio bands

Construction of the radio loudness definitions to date have been based on samples from different surveys and samples with varying properties

It is still not known which definition is statistically significant

A good fraction of QSOs classified as RL and RQ in the literature might present similar properties

Sample and data

Sample and data

Radio data:

Low Frequency Array (LOFAR)

– LOTSS [Shimwell +18 in prep., Williams+18 in prep., Duncan+18 in prep.]

~ 100 μJy sensitivity and 6 arcsec resolution

– H-ATLAS/NGP [Hardcastle +16]

~ 100 μJy sensitivity and 6 arcsec resolution

Optical data:

Sample \longrightarrow SDSS-BOSS DR12 [Alam et al. 2015, Ross et al. 2012, Paris et al. 2014]

Redshifts ($0 < z < 6$), SDSS band magnitudes (u, g, r, i, z)

Optical bolometric luminosities, black hole masses and Eddington ratios

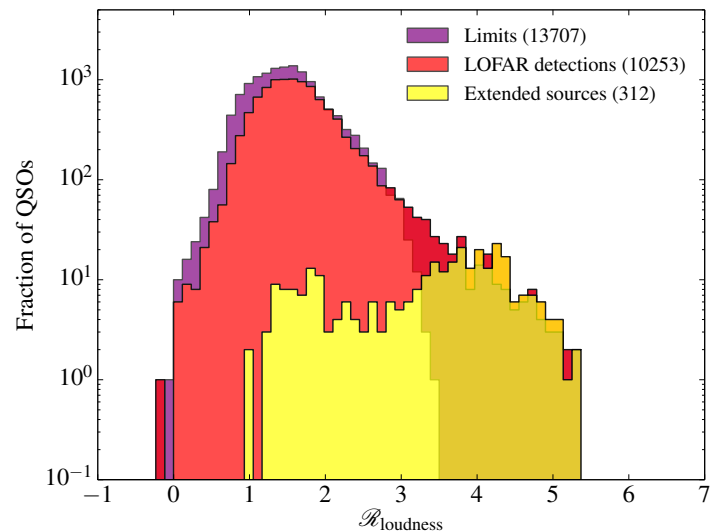

Kozlowski +17

Results – Radio loudness (\mathcal{R})

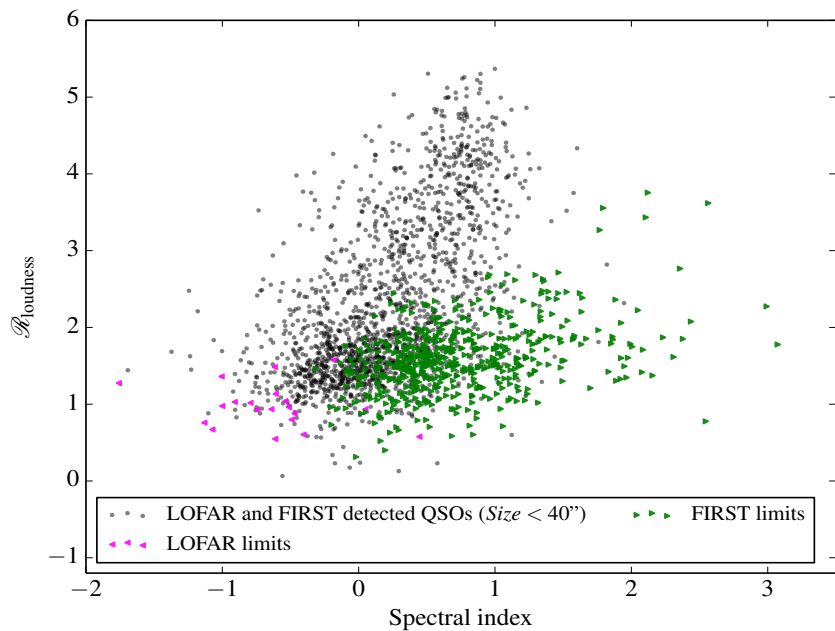

$$\mathcal{R} = \frac{L_{150}(W/Hz)}{L_{i\text{-band}}(W/Hz)}$$

Results

Results – \mathcal{R} and spectral index

Results – \mathcal{R} and SMBH parameters

Black hole masses

M_{BH} using MgII line

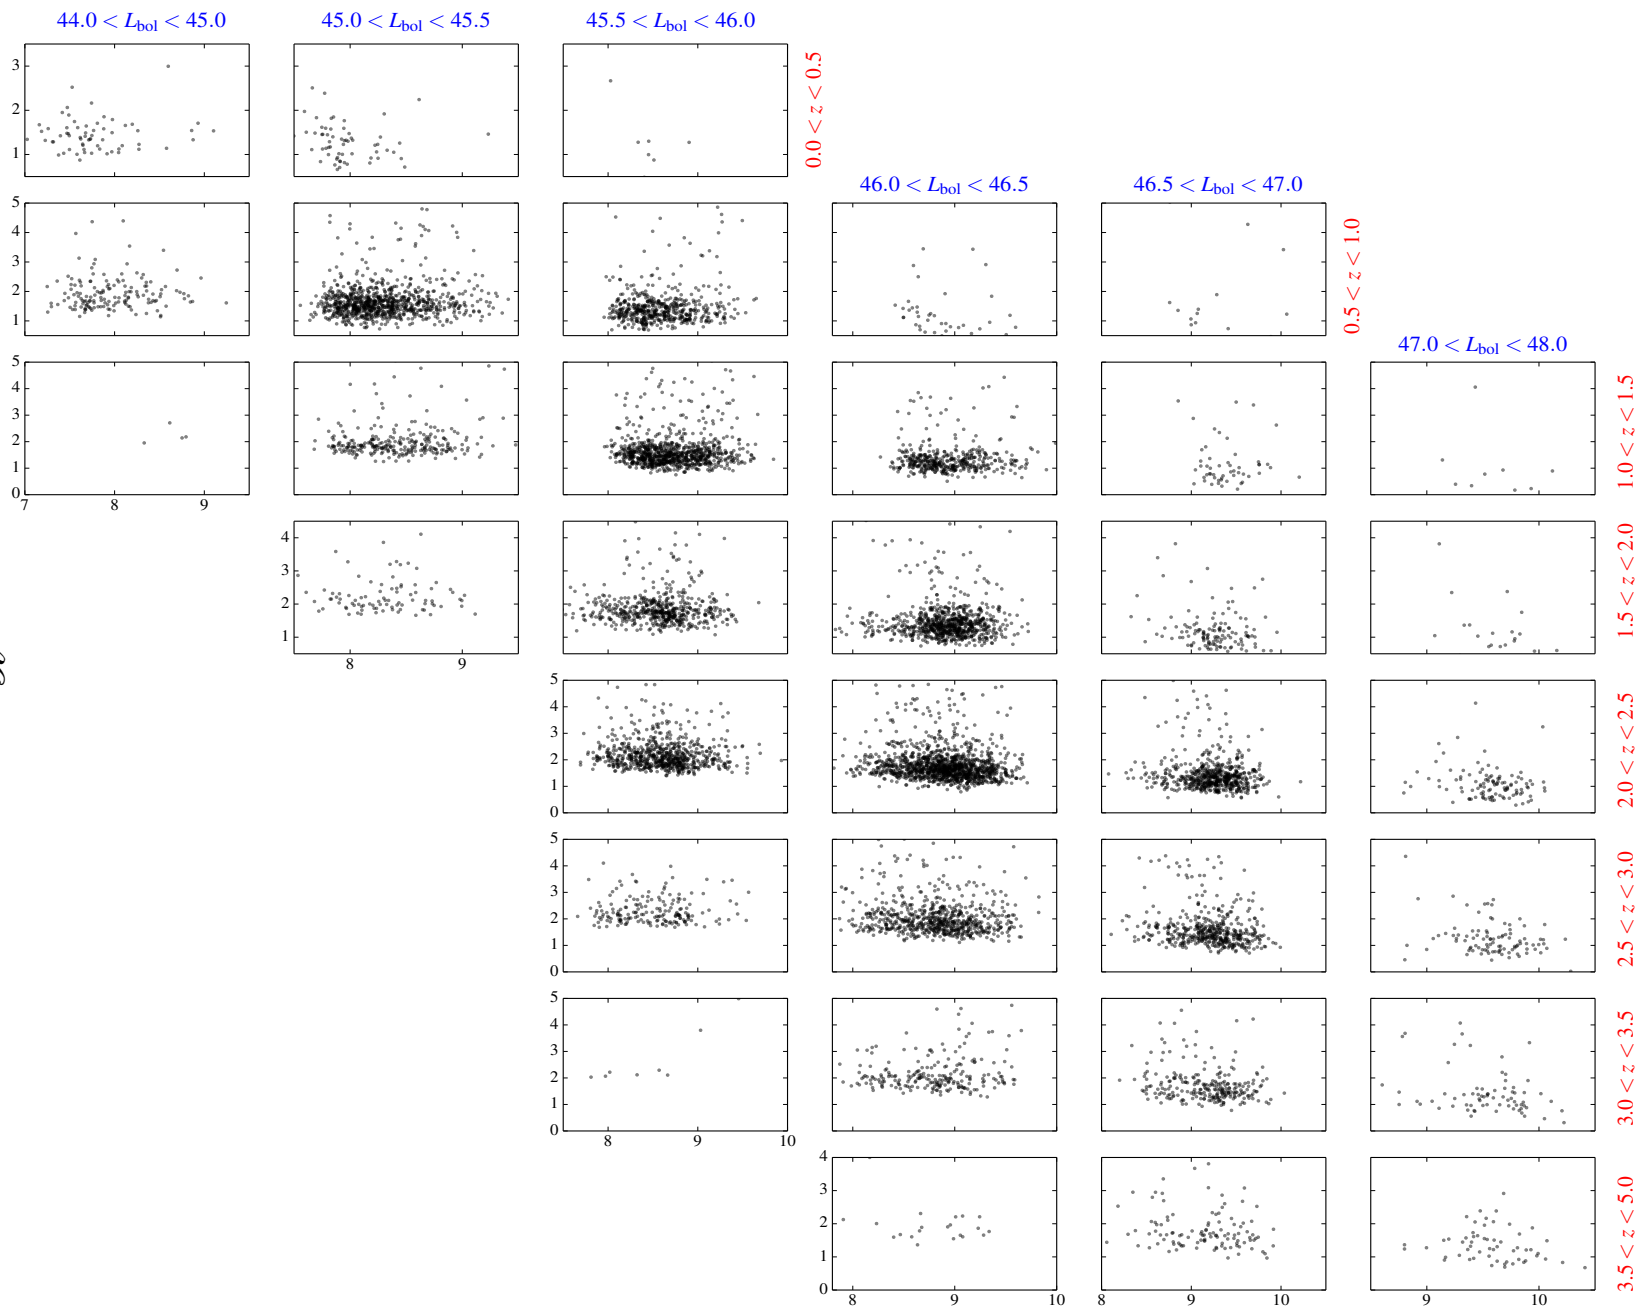

QSOs $z < 1.5$

M_{BH} using CIV line

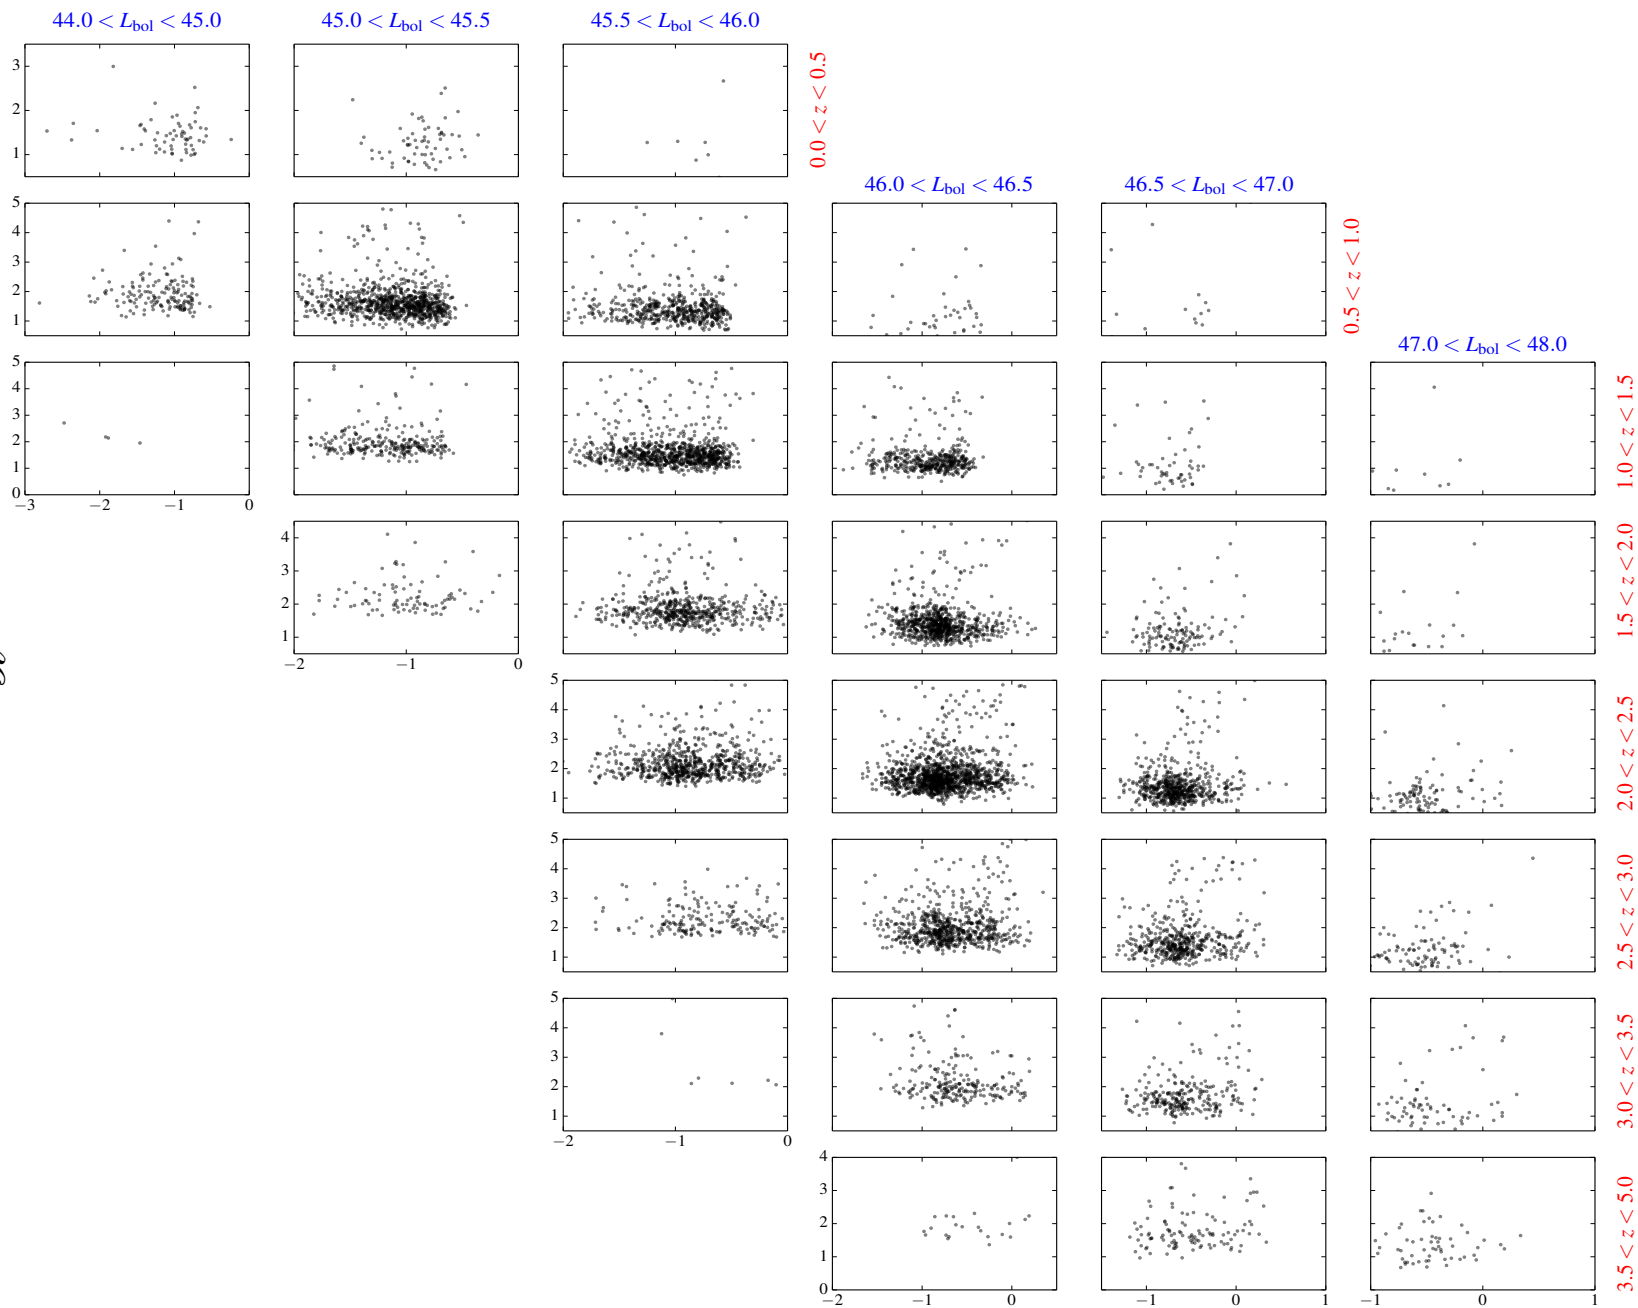

QSOs $z > 1.5$

B

\mathcal{B}

Results – the source of radio emission in QSOs

Conclusions & future work

- *Is there a radio loudness dichotomy in QSOs?*

Optically selected QSOs show a wide continuum of radio properties.

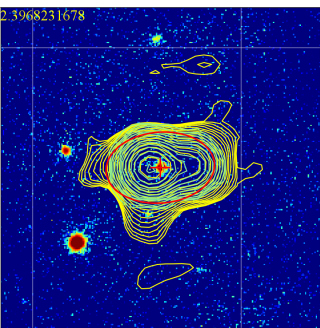

- *Does \mathcal{R} depend on any BH parameters?*

We do not observe any dependency of \mathcal{R} on either black hole mass or Eddington ratio.

- *What is the source of radio emission in optically selected QSOs?*

Contribution from star-formation?

Gurkan+18 in prep.

How about FRI QSOs?

Thank you
