DRAGNET Cluster Benchmark Numbers

Parts of the cluster and interconnects have been stress tested to optimize configuration and to find upper performance bounds that can be useful for application optimization and rough capacity estimates.

The tests described tend to cover *maximum* achievable performance results on a synthetic ideal workload. It is very likely that your (real) application will never reach these numbers, as the workload is non-ideal, and reaching peak performance can take a lot of effort. But these numbers can serve as a top reference.

Cluster Specifications

CPU computing and memory

Computing and memory numbers N/A

GPU computing, memory, PCIe

Computing numbers N/A

Memory and PCIe Bandwidth

For PCIe bandwidth, there is a substantial difference between the 2 local GPUs and the 2 GPUs local to the other CPU in the same node. NVIDIA's bandwidthTest is not meant for performance (because of GPU Boost) (as it says), but here are the numbers anyway:

```
[amesfoort@drg23 bandwidthTest]$ ./bandwidthTest --device=0
[CUDA Bandwidth Test] - Starting...
Running on...
Device 0: GeForce GTX TITAN X
Quick Mode
Host to Device Bandwidth, 1 Device(s)
PINNED Memory Transfers
Transfer Size (Bytes) Bandwidth(MB/s)
33554432 6325.2
Device to Host Bandwidth, 1 Device(s)
PINNED Memory Transfers
Transfer Size (Bytes) Bandwidth(MB/s)
```

Networking

We have benchmarked the infiniband and 10G networks. A good guide is available at the http://fasterdata.es.net/ under Host Tuning (and to a lesser extend under Network Tuning). But the indicated Linux kernel sysctl knobs did not help; CentOS 7 already has decent settings, and our transfers are all on a low latency LAN (as opposed to wide-area).

Infiniband

Each drgXX node has an FDR (54.545 Gbit/s) HCA (Host Channel Adapter) local to the second CPU (i.e. CPU id 1). The 36 port cluster switch is connected to the COBALT switch with 5 aggregated lines (272.727 Gbit/s). See below what can be achieved under ideal circumstances.

IPoIB: TCP and UDP

An application that uses the Infiniband (ib) network normally uses IPoIB (IP-over-Infiniband) to transfer data via TCP or UDP. DRAGNET IPoIB settings have been optimized for TCP (at the cost of UDP performance). We (mostly) use TCP and will not receive UDP data from LOFAR stations directly.

We used the iperf3 benchmark and got the following bandwidth numbers between two drgXX nodes:

Out-of-the-box TCP bandwidth: 26-28 Gbit/s. We can ''get iperf3'' TCP bw to 45.4 Gbit/s:

Set CPU scaling gov to 'performance' (default is 'powersave') (from 39.3 to 45.4 Gbit/s (TCP, 2 streams)) \$ for i in /sys/devices/system/cpu/cpu*/cpufreq/scaling_governor; do echo performance | sudo tee \$i; done

[amesfoort@drg23 ~]\$ sudo iperf3 -A 10 -B drg23-ib -s
[amesfoort@drg21 ~]\$ sudo iperf3 -N -4 -A 10 -B drg21-ib -i 1 -l 1M -P 2 -t
20 -c drg23-ib

-A 10: sets CPU affinity to hw thread 10. mlx_4 is on the 2nd CPU (8-15(,24-31)) and the INT handler happens to be on hw thr 9
-A 10 (or another suitable nr): from 26.2 to 45.4 Gbit/s (tcp, 2 streams)

-P 2: 2 parallel streams instead of 1: from 36.4 to 45.4 Gbit/s (tcp, -A 10)

I have extensively tried the sysctl knobs of the Linux kernel networking settings (net.core.*, net.ipv4.*, txqueuelen), but I did not get an improvement. Likely, Linux kernel autotuning + CentOS 7 settings are already ok for local area networking up to at least 45 Gbit/s.

A real application (not a synthetic benchmark) likely does something else except for data transfer and may have trouble reaching these numbers, because CPU load is a limiting factor and the clock frequency boost of 1 core on drgXX node CPUs is higher (up to 3.2 GHz) than for all cores at once (up to 2.6 GHz). Standard drgXX node CPU clock frequency is 2.4 GHz.

Numbers (before tuning iperf3 tests) obtained using qperf can be seen below under the RDMA sub-section.

RDMA

RDMA (Remote Direct Memory Access) allows an application to directly access memory on another node. Although some initial administration is set up via the OS kernel, the actual transfer commands and completion handling does not go via the kernel. This also saves data copying on sender and receiver and CPU usage.

Typical applications that may use RDMA are applications that use MPI (Message Passing Interface) (such as COBALT), or (hopefully) the LUSTRE client. NFS can also be set up to use RDMA. You can program directly into the verbs and rdma-cm C APIs and link to those libraries, but be aware that extending some code to do this is not a 1 hr task... (Undoubtedly, there is also a Python module that either only wraps or even makes makes life easier.)

We used the qperf benchmark and got the following bandwidth and latency numbers between two drgXX nodes (TCP/UDP/SCTP over IP also included, but not as fast as mentioned above):

```
[amesfoort@drg22 ~]$ qperf drg23-ib sctp bw sctp lat tcp bw tcp lat udp bw
udp lat
sctp bw:
    bw = 355 MB/sec
sctp lat:
    latency = 8.94 us
tcp bw:
    bw = 3.65 \text{ GB/sec}
tcp lat:
    latency = 6.33 us
udp bw:
    send bw = 6.12 \text{ GB/sec}
    recv bw = 3.71 \text{ GB/sec}
udp_lat:
    latency = 6.26 us
[amesfoort@drg22 ~]$ sudo qperf drg23-ib rc bi bw rc bw rc lat uc bi bw
uc_bw uc_lat ud_bi_bw ud_bw ud_lat
rc bi bw:
    bw = 11.9 \text{ GB/sec}
rc bw:
    bw = 6.38 \text{ GB/sec}
rc lat:
    latency = 5.73 us
uc bi bw:
    send bw = 12 GB/sec
    recv bw = 11.9 \text{ GB/sec}
uc_bw:
    send bw = 6.24 \text{ GB/sec}
    recv bw = 6.21 \text{ GB/sec}
uc lat:
    latency = 4.03 us
ud bi bw:
    send bw = 10.1 GB/sec
    recv bw = 10.1 \text{ GB/sec}
ud bw:
    send_bw = 5.93 GB/sec
```

```

```

```
recv bw = 5.93 GB/sec
ud lat:
    latency = 3.94 us
[amesfoort@drg22 ~]$ sudo gperf drg23-ib rc rdma read bw rc rdma read lat
rc rdma write bw rc rdma write lat rc rdma write poll lat uc rdma write bw
uc rdma write lat uc rdma write poll lat
rc rdma read bw:
    bw = 5.6 \, GB/sec
rc rdma read lat:
    latency = 4.99 us
rc rdma write bw:
    bw = 6.38 \text{ GB/sec}
rc rdma write lat:
   latency = 5.35 us
rc rdma write poll lat:
   latency = 925 ns
uc rdma write bw:
    send bw = 6.26 \text{ GB/sec}
    recv bw = 6.23 GB/sec
uc rdma write lat:
   latency = 3.58 us
uc rdma write poll lat:
    latency = 922 ns
[amesfoort@drg22 ~]$ sudo qperf drg23-ib rc compare swap mr rc fetch add mr
ver_rc_compare_swap ver_rc_fetch_add
rc compare swap mr:
    msg_rate = 2.08 M/sec
rc fetch add mr:
    msg rate = 2.14 \text{ M/sec}
ver rc compare swap:
    msg rate = 2.1 \text{ M/sec}
ver rc fetch add:
    msg rate = 2.4 \text{ M/sec}
```

10 Gbit/s Ethernet

The drgXX and dragproc nodes have a 10 Gbit/s ethernet adapter local to the first CPU (i.e. CPU id 0). A 48 port Ethernet switch is connected to a LOFAR core switch with 6 aggregated lines (60 Gbit/s). See below what can be achieved under ideal circumstances.

One should be able to achieve (near) 10 Gbit/s using a TCP socket stream. The iperf benchmark achieves 9.91 Gbit/s.

The 6x 10G trunk is apparently not able to utilize all 6 links simultaneously with up to 10 streams (some info on the why is available, but off-topic here). The following is what can be max expected for applications between DRAGNET and COBALT across 10G:

```
DRAGNET -> COBALT, 8x iperf TCP: 38.8 Gbit/s. Second run: 39.7 Gbit/s. (Aug
2015)
```

And a week later we achieved 10G higher throughput using 10 COBALT and 10 DRAGNET nodes. Commands: iperf -N -B 10.168.130.1 -s and iperf -N -B 10.168.96.1 -c 10.168.130.1 -i 1

DRAGNET -> COBALT (1 iperf TCP stream per node) (6x10G) (otherwise idle clusters and network) (Sep 2015) bandwidth (Gbit/s) #streams 9.91 (1 full bw) 1 2 19.82 (2 full bw) 3 29.73 (3 full bw) 4 29.76 (2 full bw, 2 ~half bw) 5 29.68 (1 full bw, 4 ~half bw) 6 39.54 (2 full bw, 4 ~half bw) 7 49.49 (3 full bw, 4 ~half bw) (best result, 47-49.5) 8 46.19 (1 full bw, 7(?) ~half bw) (best result after 6 runs, half of the runs didn't do 8 streams) 9 49.28 (1 full bw, 8 ~half bw) 10 49.13;50.52 (0 full bw, 10 ~half bw) COBALT -> DRAGNET (1 iperf TCP stream per node) (6x10G) (otherwise idle clusters and network) (Sep 2015) #streams bandwidth (Gbit/s) 9.91 (1 full bw) 1 2 19.82 (2 full bw) 3 19.82;9.92 (2 full bw, 2 ~half; or 3x 1/3rd) 4 29.72 (2 full bw, 2 ~half) 5 39.64 (3 full bw, 2 ~half) (better than dragnet->cobalt #streams=5) 49.52 (4 full bw, 3 2-3G, 1 near <1G) 8 10 48.87 (3 full bw, the rest 2-3 G)

From 16 CEP2 nodes equally spread over the 4 CEP2 switches to 16 DRAGNET nodes (Sep 2015), iperf got us in 3 test runs:

Total iperf (synthetic/benchmark) bandwidth for each test after initial ramp-up (~8 s): 48.02 Gbit/s 41.97 Gbit/s 44.84 Gbit/s If you'd transfer large, equal sized files, some files in a set of 16 would be transferred way earlier than others, since some indiv streams reached only 1 Gbit/s, while others reached 5 Gbit/s.

Doing this with 14 LOTAAS .raw files data using scp from CEP2 \rightarrow DRAGNET is not going to be blazingly fast:

time \
