# **DRAGNET Cluster Support Info**

- The DRAGNET cluster was delivered on Thu+Fri 9+10 July 2015.
- We have 4 years support on the complete system.
- ⇒ DRAGNET cluster support ends in July 2019.

# **Failing Components**

After initial post-delivery replacements, hard drives fail the most often (as expected). As of writing (Aug 2017), we have been through 3 replacement calls (only a few drives each time) + 1 upcoming. Other defective components can be reported via the support site or by e-mail. Please also provide some "proof" that it is defective, or discuss with them how to do that (possibly after reading their service support Tips/Troubleshooting/... pages).

For up to 20 drives, our vendor wants defective *hard drives* to be reported via their service site (instead of by e-mail). For the service we did so far, we don't need service credits (as long as our support contract lasts).

Log in, then:

- Click on one of the support call links at the bottom of the page. E.g. for hard drives:
- Verify shipping address for return parts, then fill in:
- ClusterVision machine tag: 150037 (I'm entirely unsure about this, but it doesn't matter.)
- Your machine reference: drg02 drg12 drg16
- Hard Disk Brand: TOSHIBA
- Hard Disk Model: MC04ACA400E
- Hard Disk Serialnumbers: 5517K0XUFLSA 551AK0N0FLSA 551AK0NEFLSA (example)
- Number of Hard Disks with Failures: 3
- Linux Kernel Version: uname -a command output, e.g.: Linux drg02 3.10.0-229.el7.x86\_64 #1 SMP Fri Mar 6 11:36:42 UTC 2015 x86\_64 x86\_64 x86\_64 GNU/Linux

#### Hardware Settings:

- 1. Has the BIOS configuration been set to AHCI ?: yes
- 2. Is the disk part of an array on a dedicated hardware RAID controller?: no
- 3. Have you tried to fully re-provision the software onto the disk?: yes

Fault Description - Please use this part for all disks.:

```
[root@drg02 ~]$ smartctl --all /dev/sdb
smartctl 6.2 2013-07-26 r3841 [x86_64-linux-3.10.0-229.el7.x86_64] (local build)

```

#### **Hard Drives**

The smartd service has been set up on all DRAGNET nodes to auto-report S.M.A.R.T. (self-monitoring for hard drives) failures (actually counters exceeding certain thresholds) by e-mail to dragnet[AT]astron[DOT]nl.

Note 1: By definition you cannot fully (or at all) count on such predictive failure analysis.

*Note 2*: To avoid endless spam, only 1 e-mail is sent. Another one for every new extended test failure or threshold exceeded.

To dump all S.M.A.R.T. information for a drive to a .log file, run (as root or via sudo):

```
$ smartctl --all /dev/XXX >> smartctl-xxx.log
```

On drgXX nodes, XXX is one of: sda, sdb, sdc, sdd.

On the dragnet head node, XXX is one of sg1, sg2 (requires kernel module sg loaded, but this is the case by default).

Note that the dragproc node has a RAID controller that needs some magic:

```
\ for i in 10 11 9 8 12 13 15 14; do echo "Device ID=$i" && sudo smartctl -- all -d megaraid,$i /dev/sda; done >> smartctl-xxx.log
```

These numbers correspond to the RAID controller's connected drive IDs. In case you want to check or if it changed, you can display these IDs with a special tool called storcli; see Alexander's shell log at the end of this wiki page.

To start an extended S.M.A.R.T. check, run (as root or via sudo):

### \$ smartctl --test=long /dev/XXX

(XXX as well as dragproc magic described above apply here too.)

You may continue working, send the same command to the next drive, or even reboot. The drive will continue when no other requests are there. An extended test may take many hours. Afterwards, you can show the S.M.A.R.T. information again to see the result, but if a failure threshold was exceeded, our smartd service also sends an e-mail.

#### **Upon Drive Failure**

Tip 1: when drives fail, first:

**1.** remount the covering partition read-only:

\$ sudo mount -o remount, ro /dev/mdX # where mdX is the software RAID partition that covers your suspicious drive. You can find X using the ''lsblk'' command.

The system may protest if files are open in read-write mode. It depends on the situation what to do (ask, kill, wait), but you can find the offending process using the lsof command (typically as root; Note: long output!).

2. backup data elsewhere (duh)

*Tip 2*: when 1 drive fails, run an extended S.M.A.R.T. check on all drives on the cluster to minimize the number of support requests and data center visits.

Important: All drives have a Device Model nr and a Serial Number, etc. Ensure you (Cpt. obvious):

- first report the right IDs + copy-paste the S.M.A.R.T. logs from the right drive
- then replace the right drive in the data center(!) (ask Mike Sipior how to flash the right drive lights, etc)
- then return ship the drive(s) with the reported ID(s)!

Then you need to:

- restore the broken RAID (on drgXX) (ask Mike Sipior, or use the mdadm command (display of healthy state shown below), then instruct kernel to reload partition tables using the partprobe command)
- remount the partition (/dev/mdX to /data[12])
- copy back the backed up data
- once you're sure the backup is no longer needed, delete it

## Shipping and Return

08:26

If accepted, our vendor generally sends a replacement within 1 working day, provided they have replacements in stock. They also send a UPS label for easy return shipping of the defective component (to their return address in Amsterdam).

Work with Derk Kuipers or someone else at the ASTRON stockroom to send (and pick up) packages. If you have no (valid) UPS label, get a blank label from the reception.

#### **Data Center Visit**

For disk replacement, one person is enough. If the node has to be opened up, 2 persons are needed (sliding rails issue + node weight + limited space in data center).

# **Overview Examples of mdadm and Isblk**

How it should look on drgXX nodes, example on drg22 from Aug 2017):

```
[amesfoort@drg22 ~]$ sudo mdadm --detail /dev/md1 /dev/md2
/dev/md1:
