

LOFAROPS – 3C295 data analysis:

HBA-low SEFD data
and bandpass ripple

Ger de Bruyn

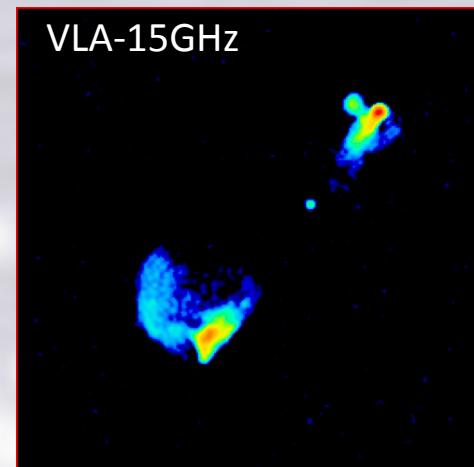

with some help from Oscar Martinez and Andre Gunst

3C295 data analysis

RA= 14h 12m Dec = +52° 12'! → < 1° from zenith !

Adopted flux density in HBA-low (115-163 MHz) :

$$S = 100 (\nu / 125 \text{ MHz})^{-0.5} \text{ Jy}$$

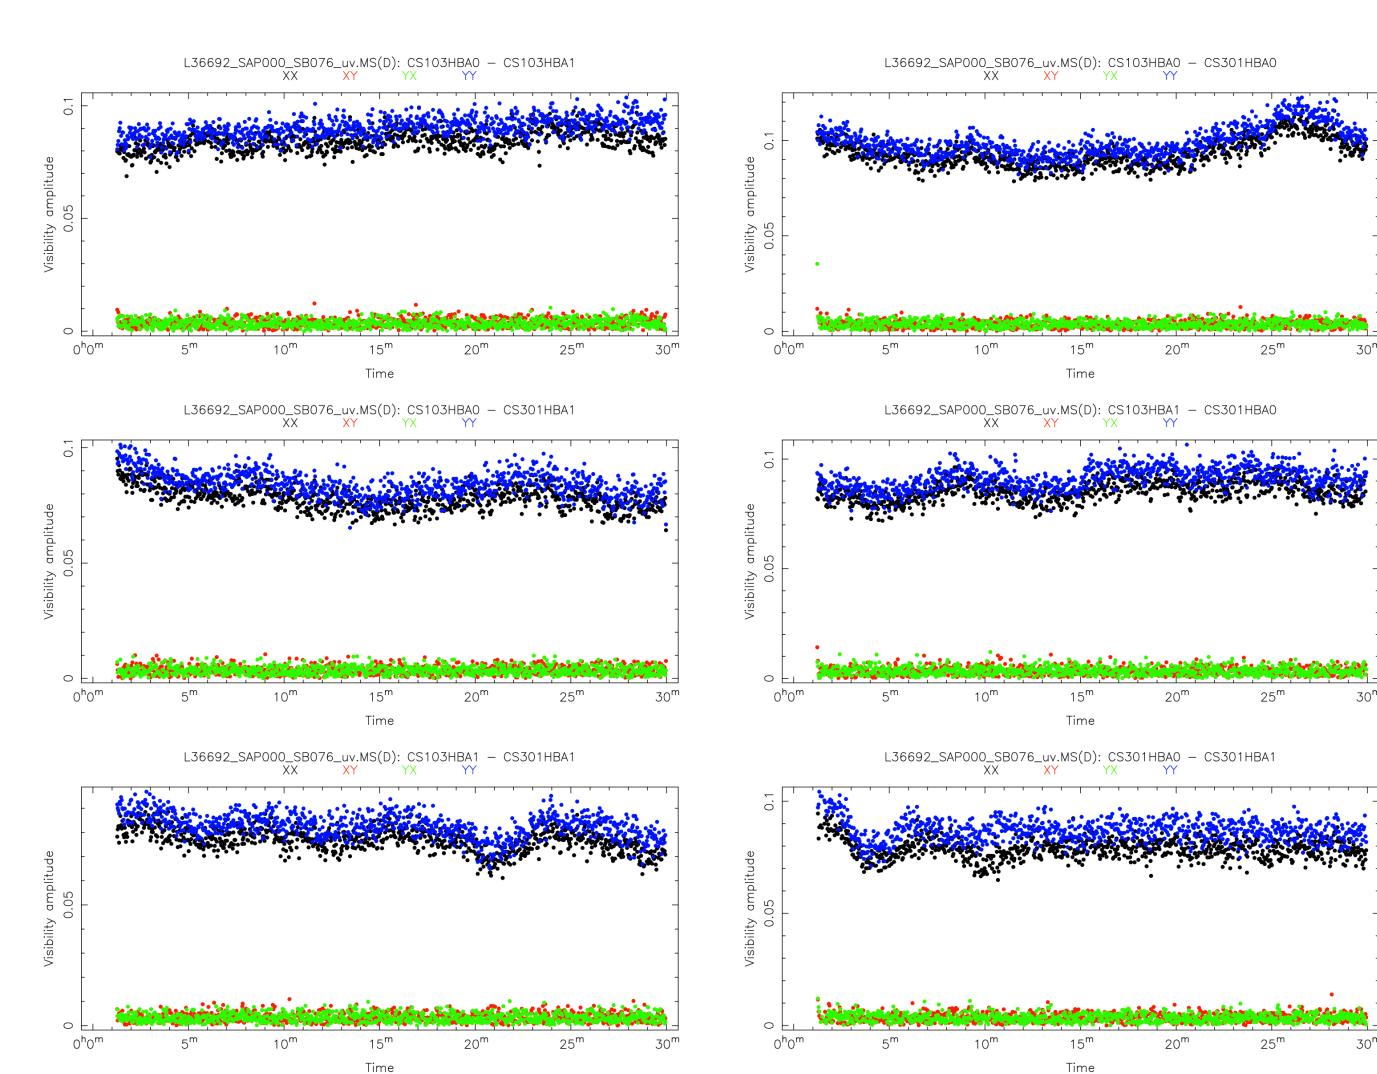

5" double

Visibility data have been used to study:

- 1) Data quality/stability on various CS and RS stations (Oct11 – Jan12)
- 2) Overall noise in the HBA-band (120-168 MHz, RCU Mode5)
- 3) Bandpass shape and ~ 1 MHz ripple

Todays analysis using data from: L36692 13 Dec 2011 (UT 1145-1215)

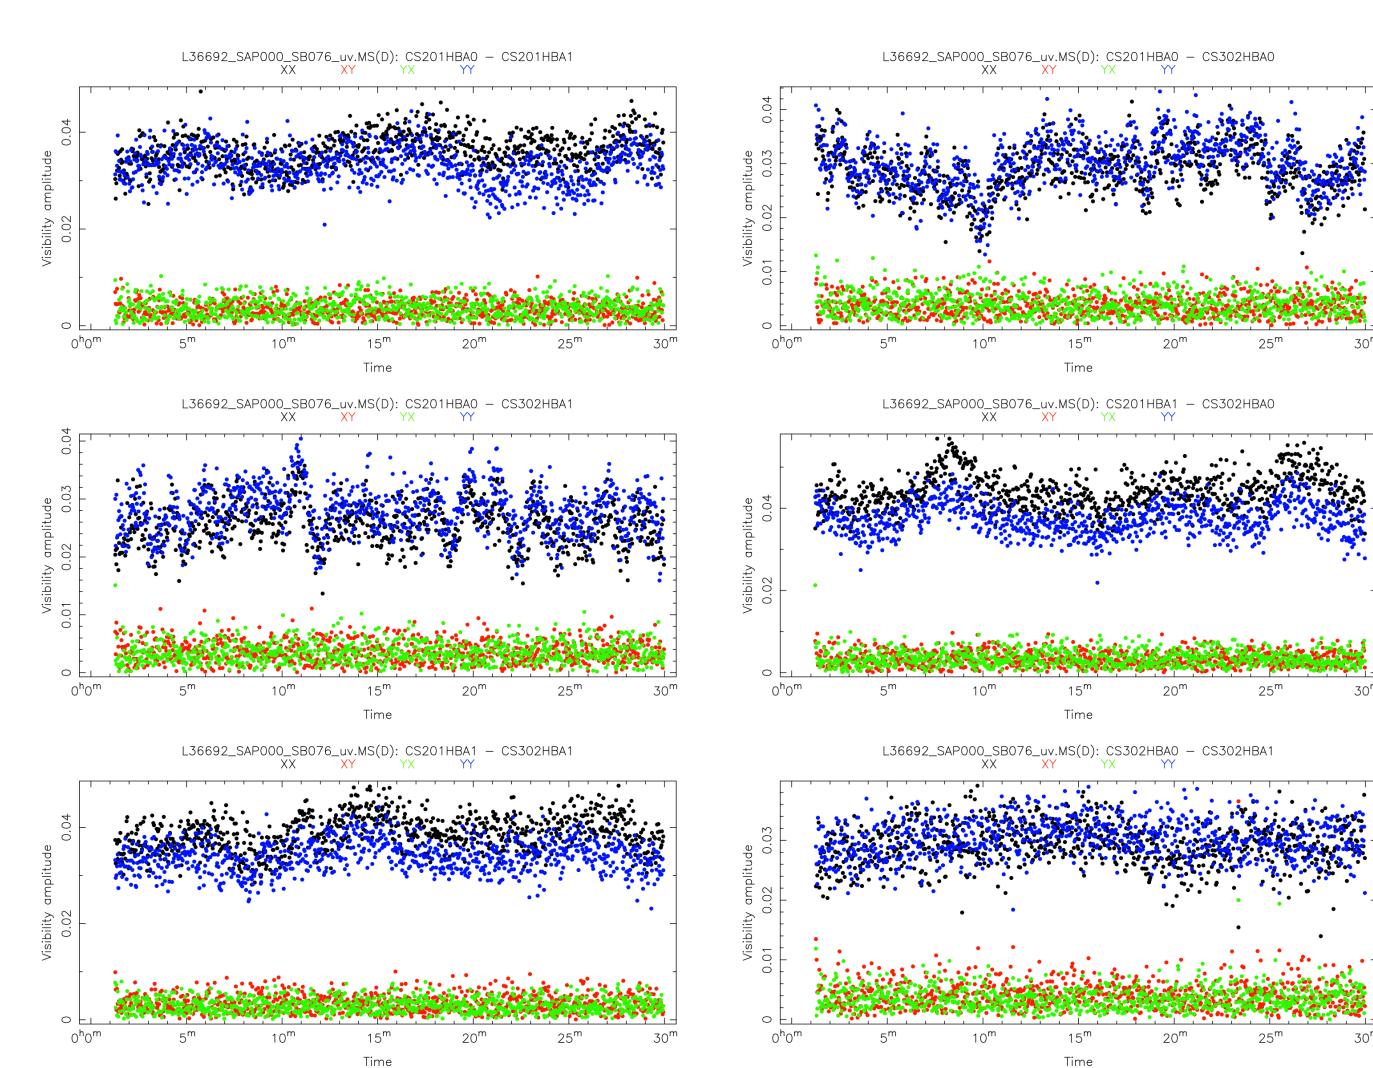

Good stations: CS103 HBA0/1 and CS301 HBA0/1

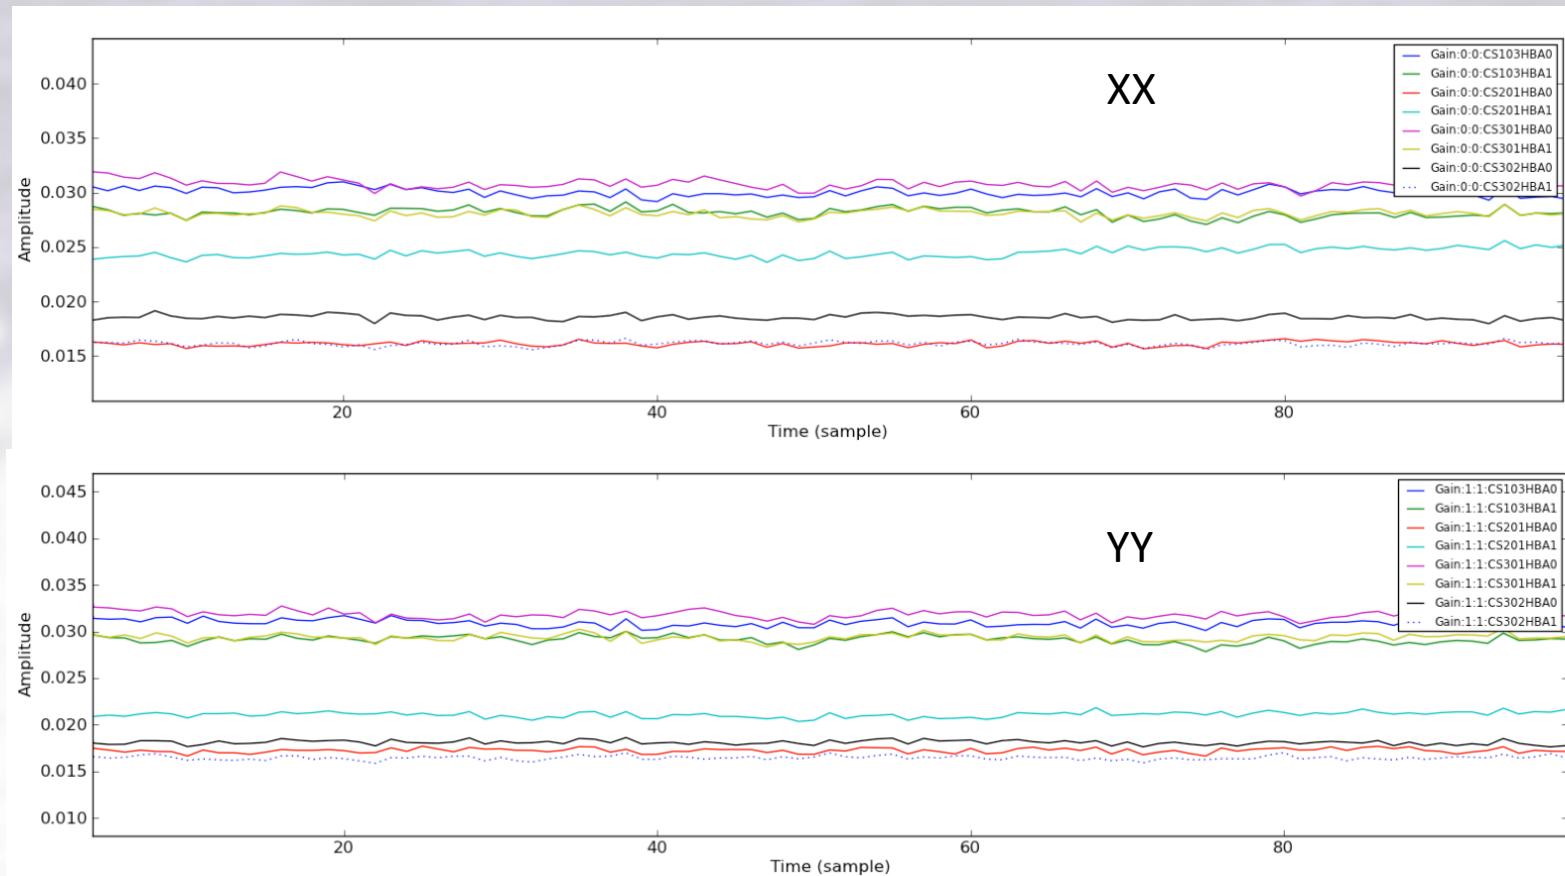

135 MHz

2s

Bad stations: CS201 HBA0/1 and CS302 HBA0/1

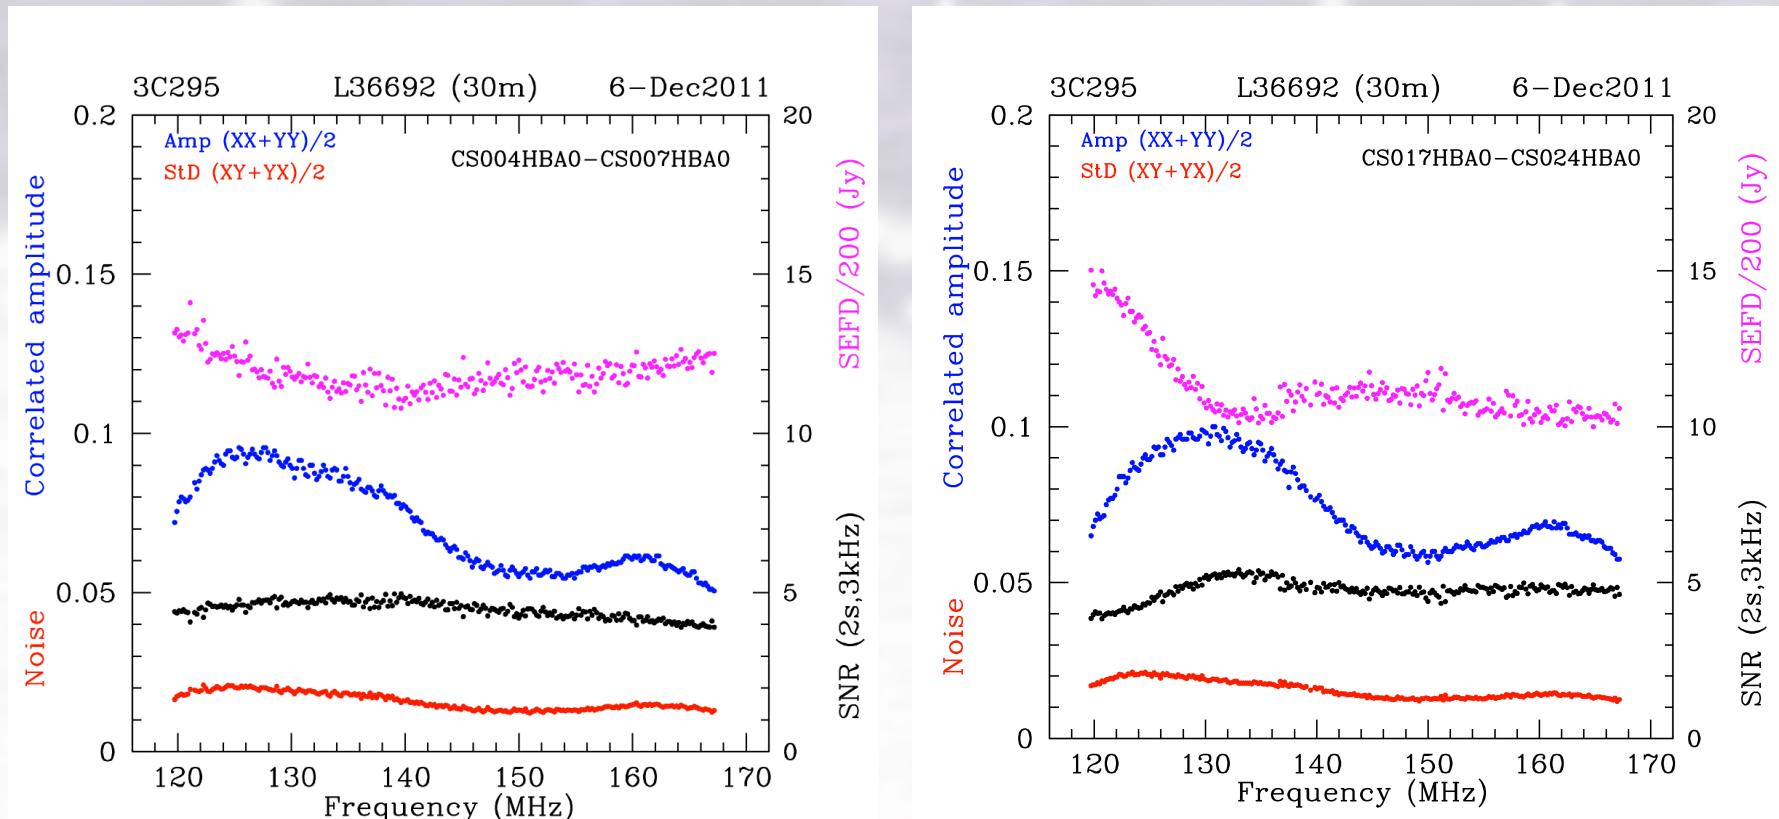

SNR ratios determined from raw visibility
scale approximately as $(\text{BBS-gains})^{-2}$

Bandpass, SNR and SEFD versus frequency

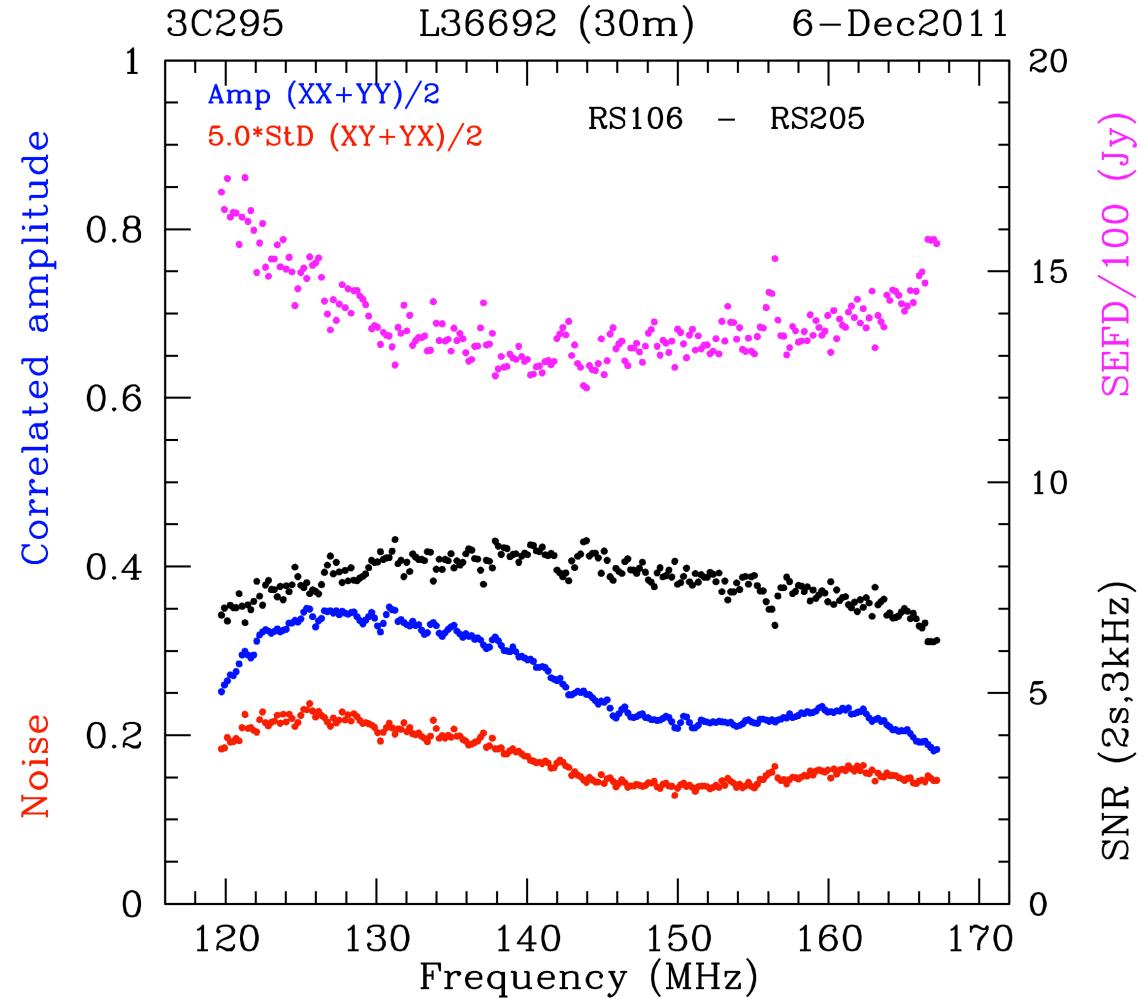

Data transferred to and processed on EoR cluster using scripts of Oscar Martinez Rubi

$$\sigma = \text{SEFD} / \sqrt{2 \Delta\nu \cdot \Delta\tau}$$

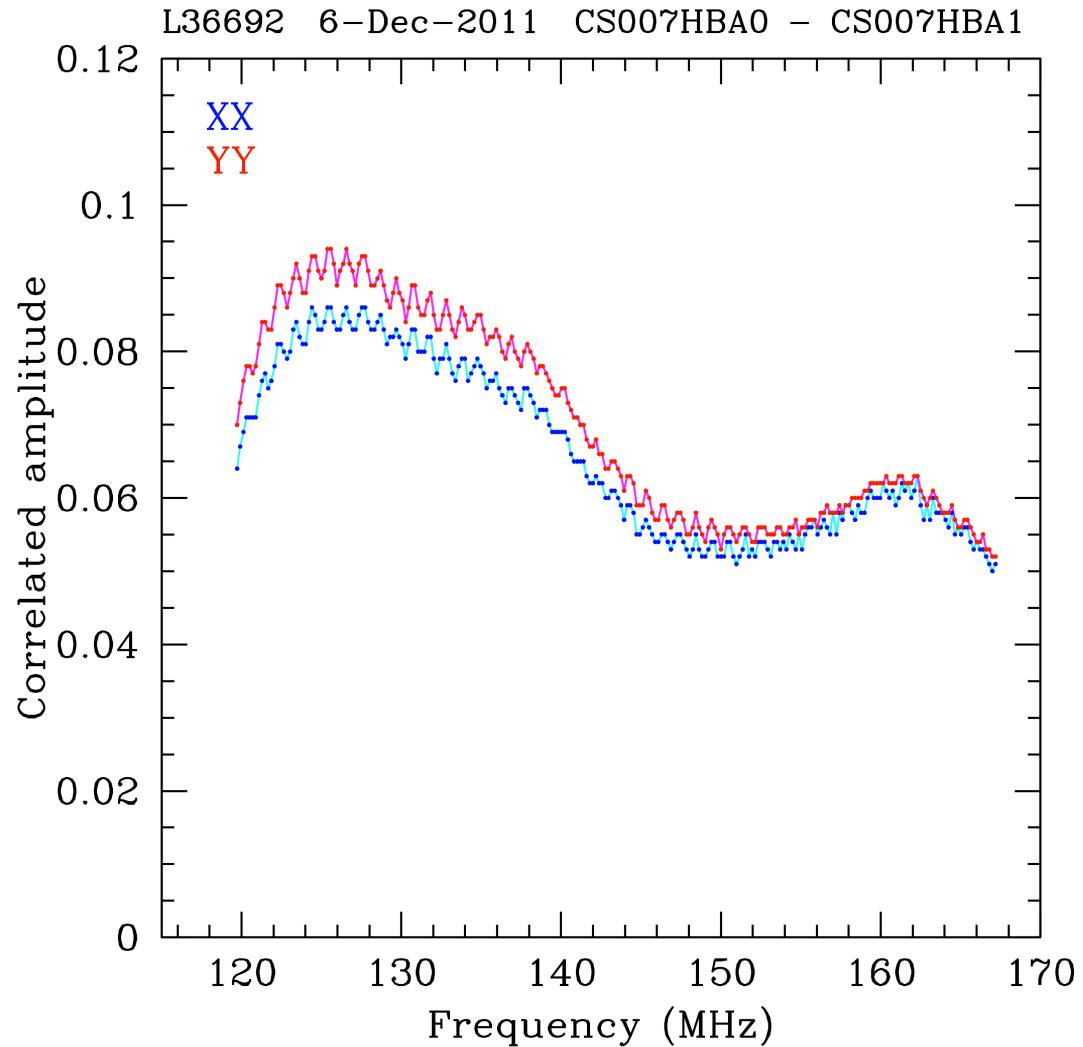

1 pol

Bandpass and SEFD on Remote Stations

1300 Jy

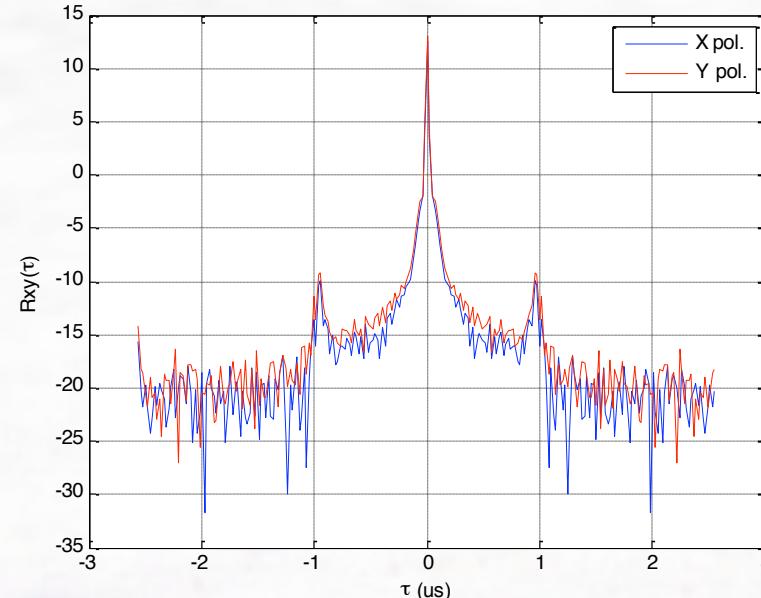

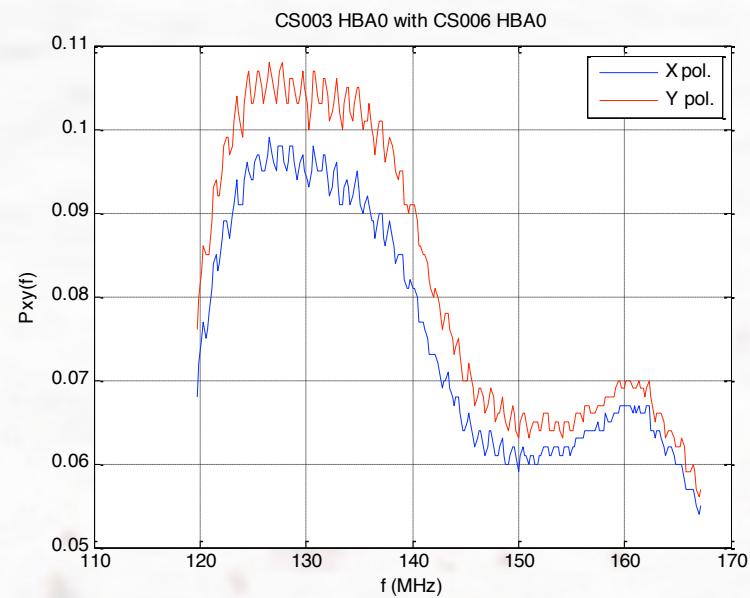

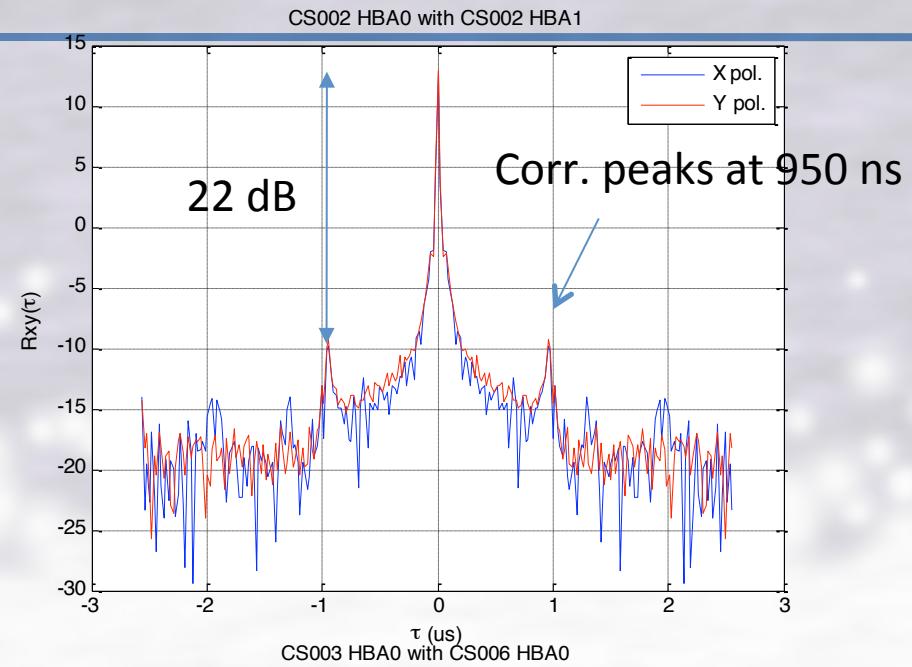

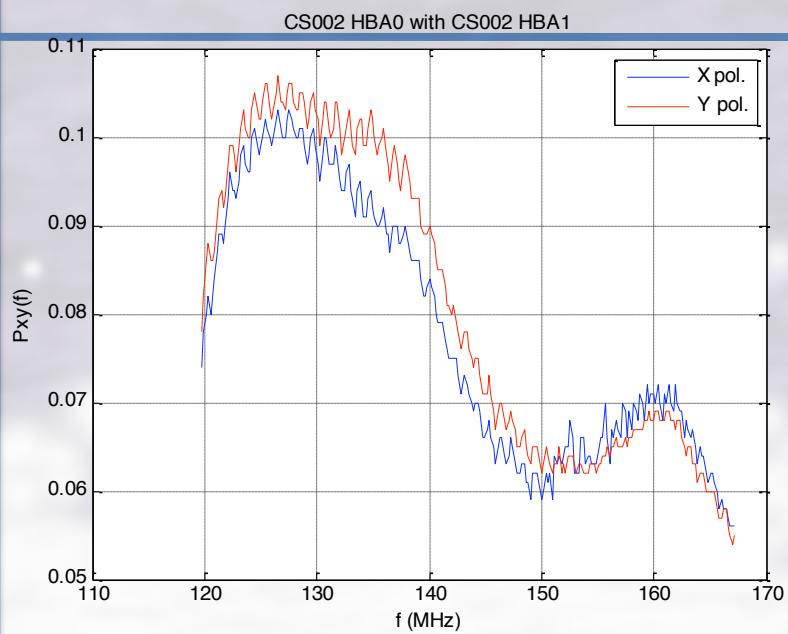

Detailed HBA-low bandpass shape

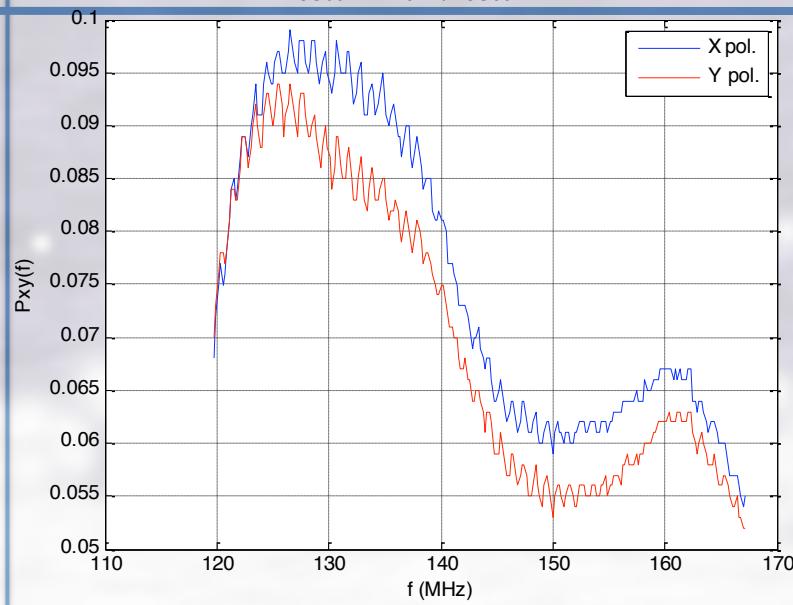

Approximately 1 MHz
ripple

In both XX and YY

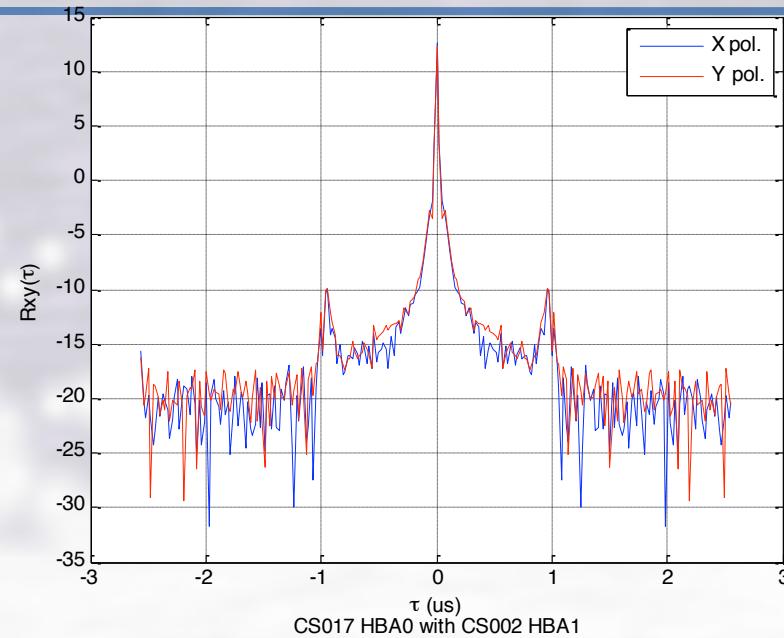

Amplitude decreases
slightly with frequency

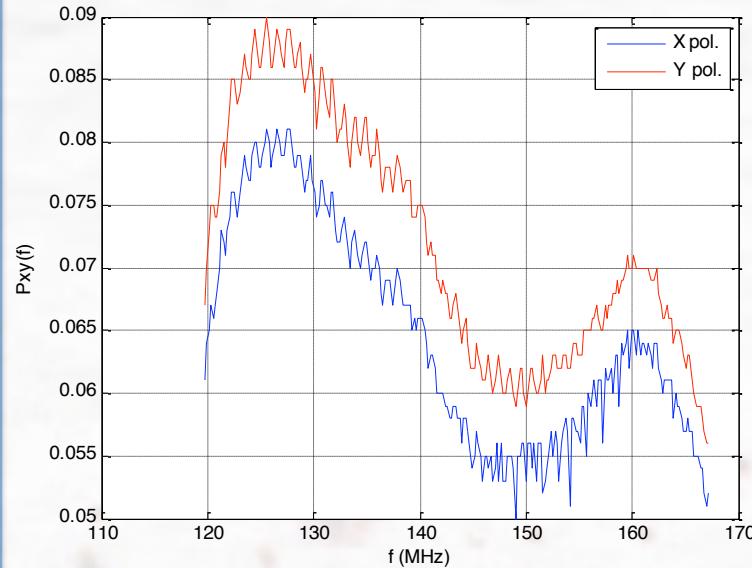

CS007 HBA0 with CS007 HBA1

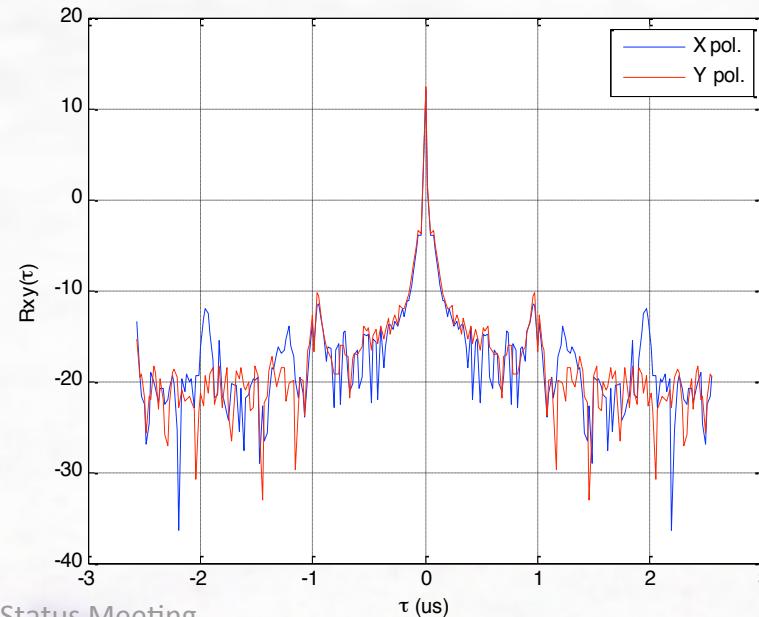

CS007 HBA0 with CS007 HBA1

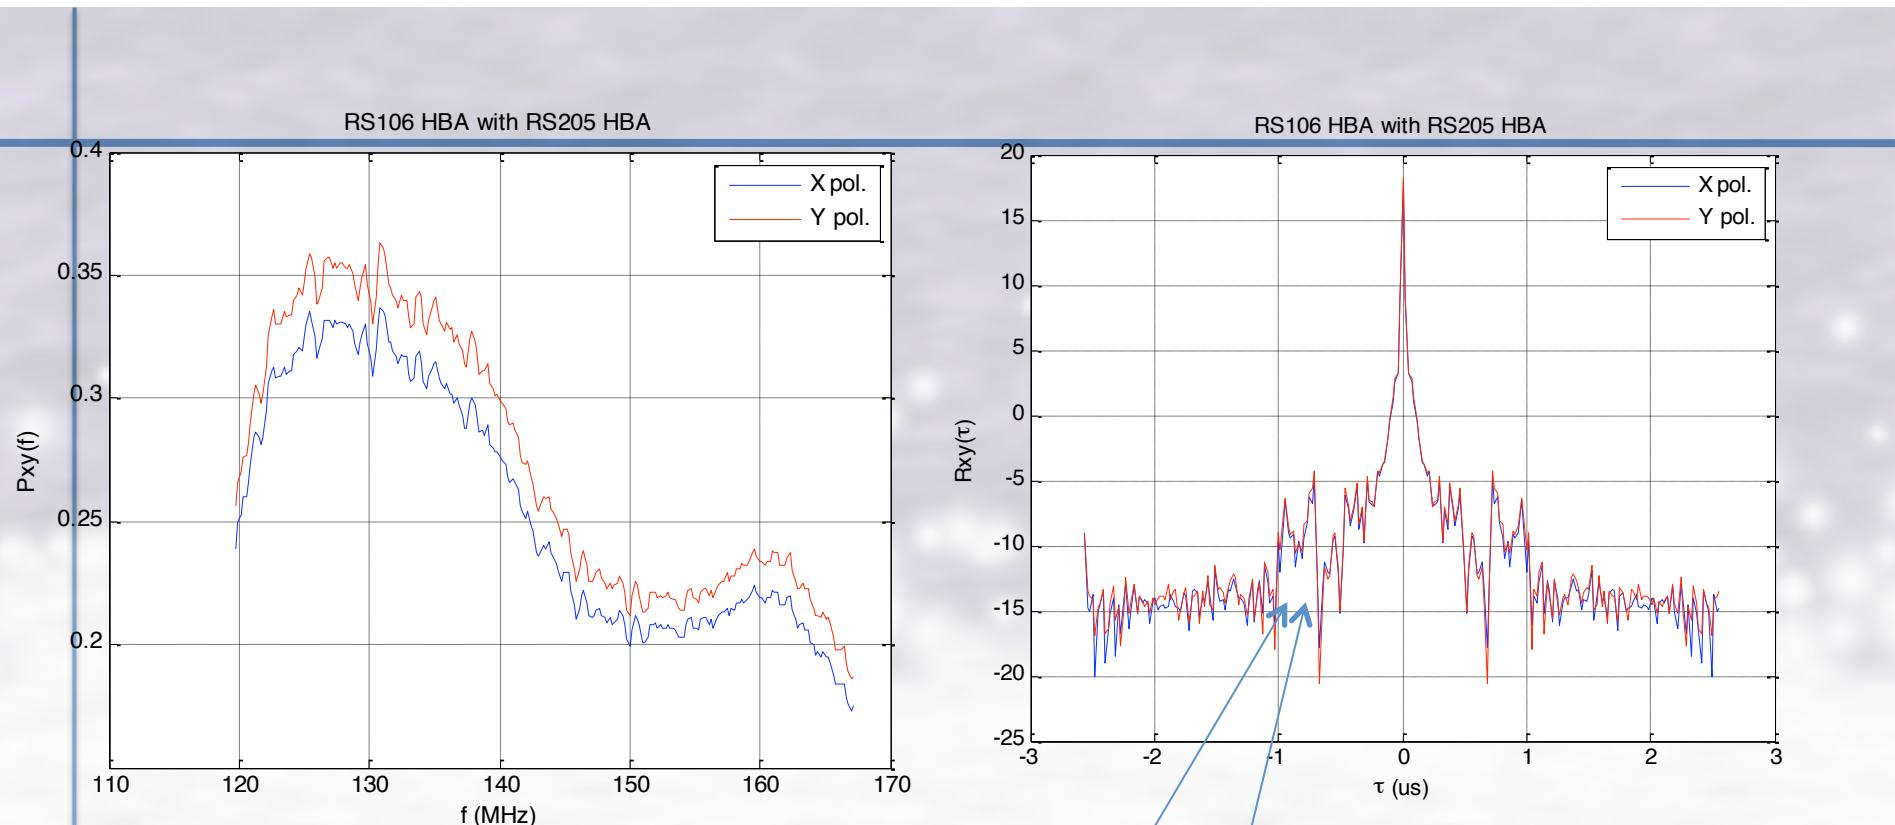

CS017 HBA0 with CS017 HBA1

CS017 HBA0 with CS002 HBA1

720 ns

950 ns

Frequency ripple, and corresponding time delays, due to coax cable length of 85 m and 115 m respectively (signal speed $\sim 0.8 c$)

Signals get reflected at RCU (~ 7 dB), suffer 2x 6dB transmission loss $\rightarrow \sim 20$ dB

Conclusions

Regular 30m-monitoring of 3C295 (amp, phase, bandpass)

Broad-band zenith HBA SEFD-values of **good** stations (130-160 MHz)

CS ~ 2200-2400 Jy

RS ~ 1300 Jy

Many stations factor 2-4 worse → under investigation (cal tables?)

HBA-low bandpass ripples:

~ 1 MHz ripple on CS (115 m cables)

~ 1 and 1.4 MHz ripple on RS (85 and 115 M cables)

Stability/calibratability of this ripple under investigation
