

Study on Correlation Artefacts Generated by the Station Power Supply System

Stefan J. Wijnholds

e-mail: wijnholds@astron.nl

**LOFAR Status Meeting
Dwingeloo, 19 August 2009**

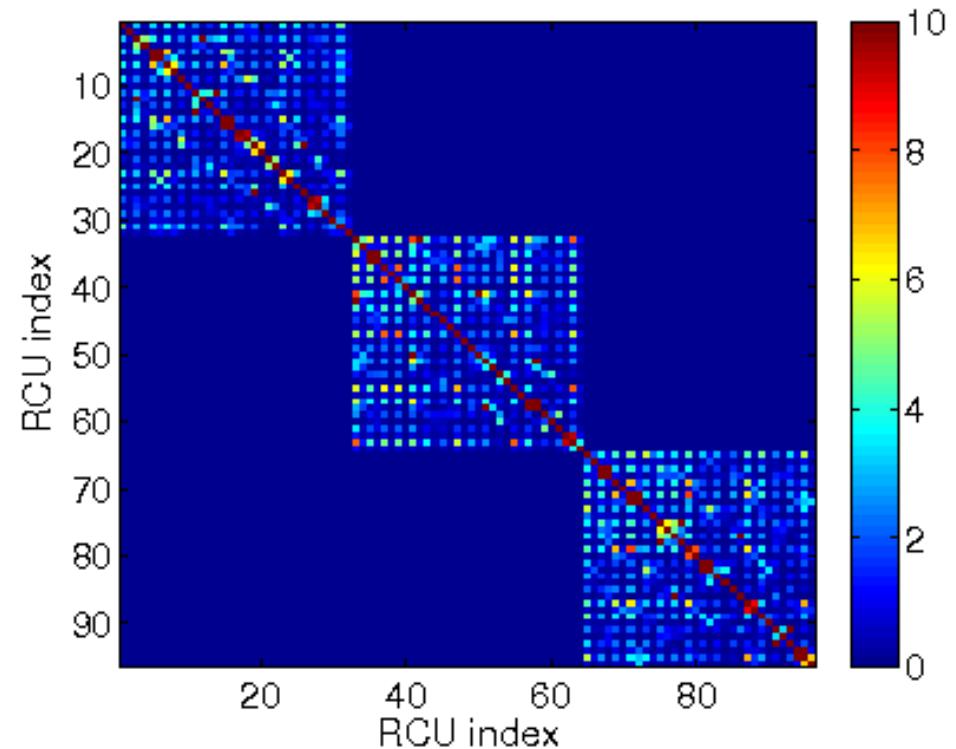

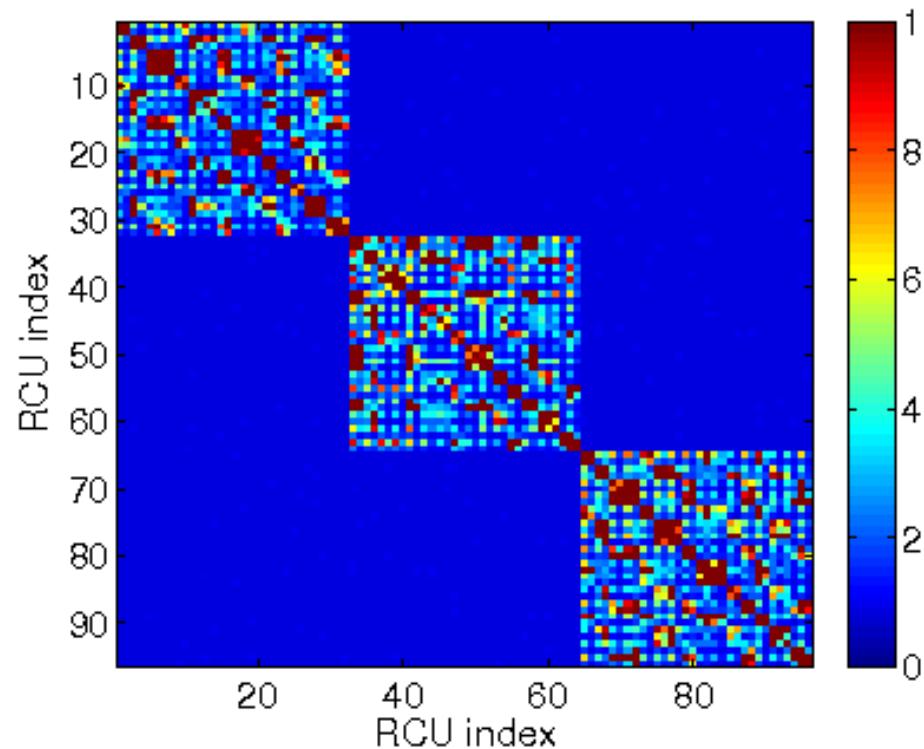

PM: HBA crosstalk measurements (1)

Stefan J. Wijnholds, LSM, 8 July 2009

ASTRON

single frequency sweep, 64 s integration per subband

average absolute value (l) and absolute average value (r)

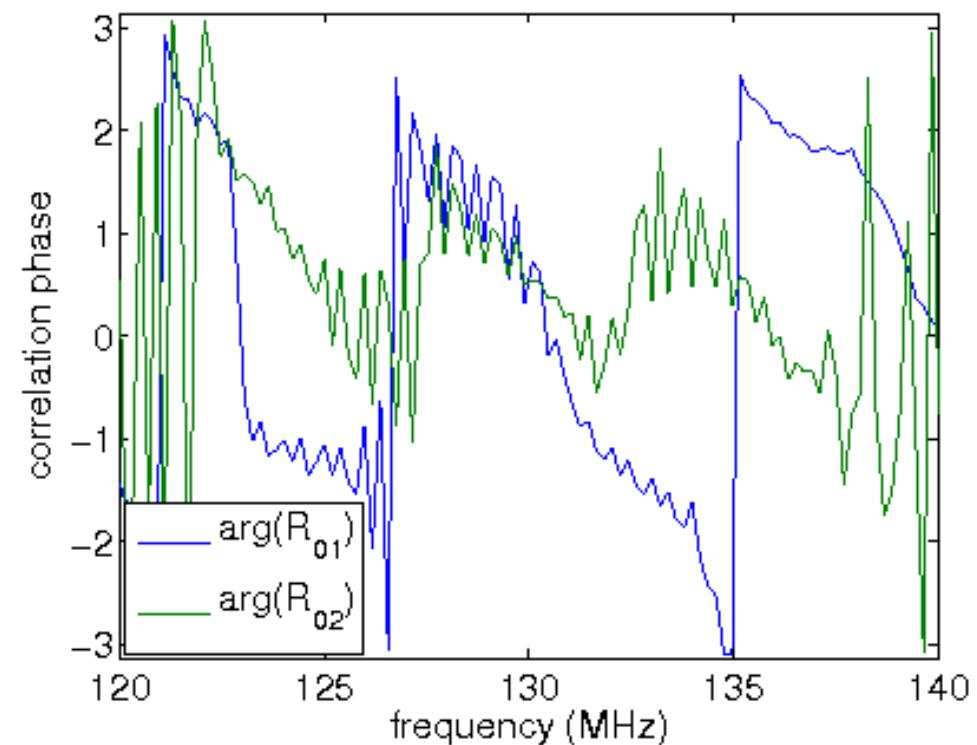

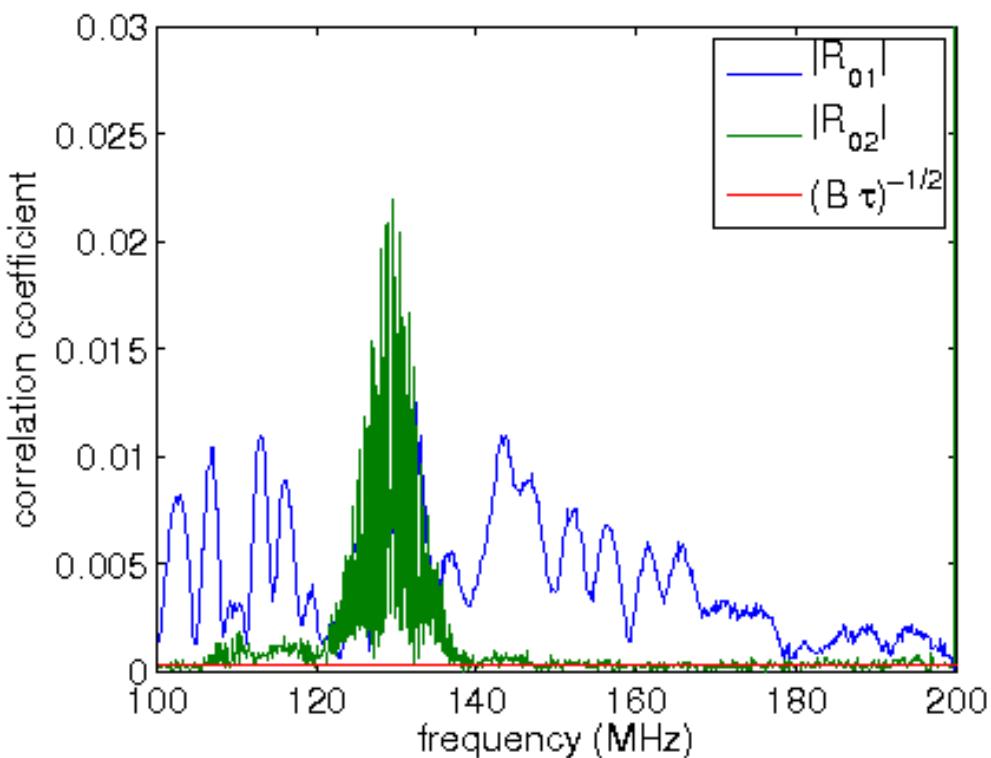

PM: HBA crosstalk measurements (2)

Stefan J. Wijnholds, LSM, 8 July 2009

ASTRON

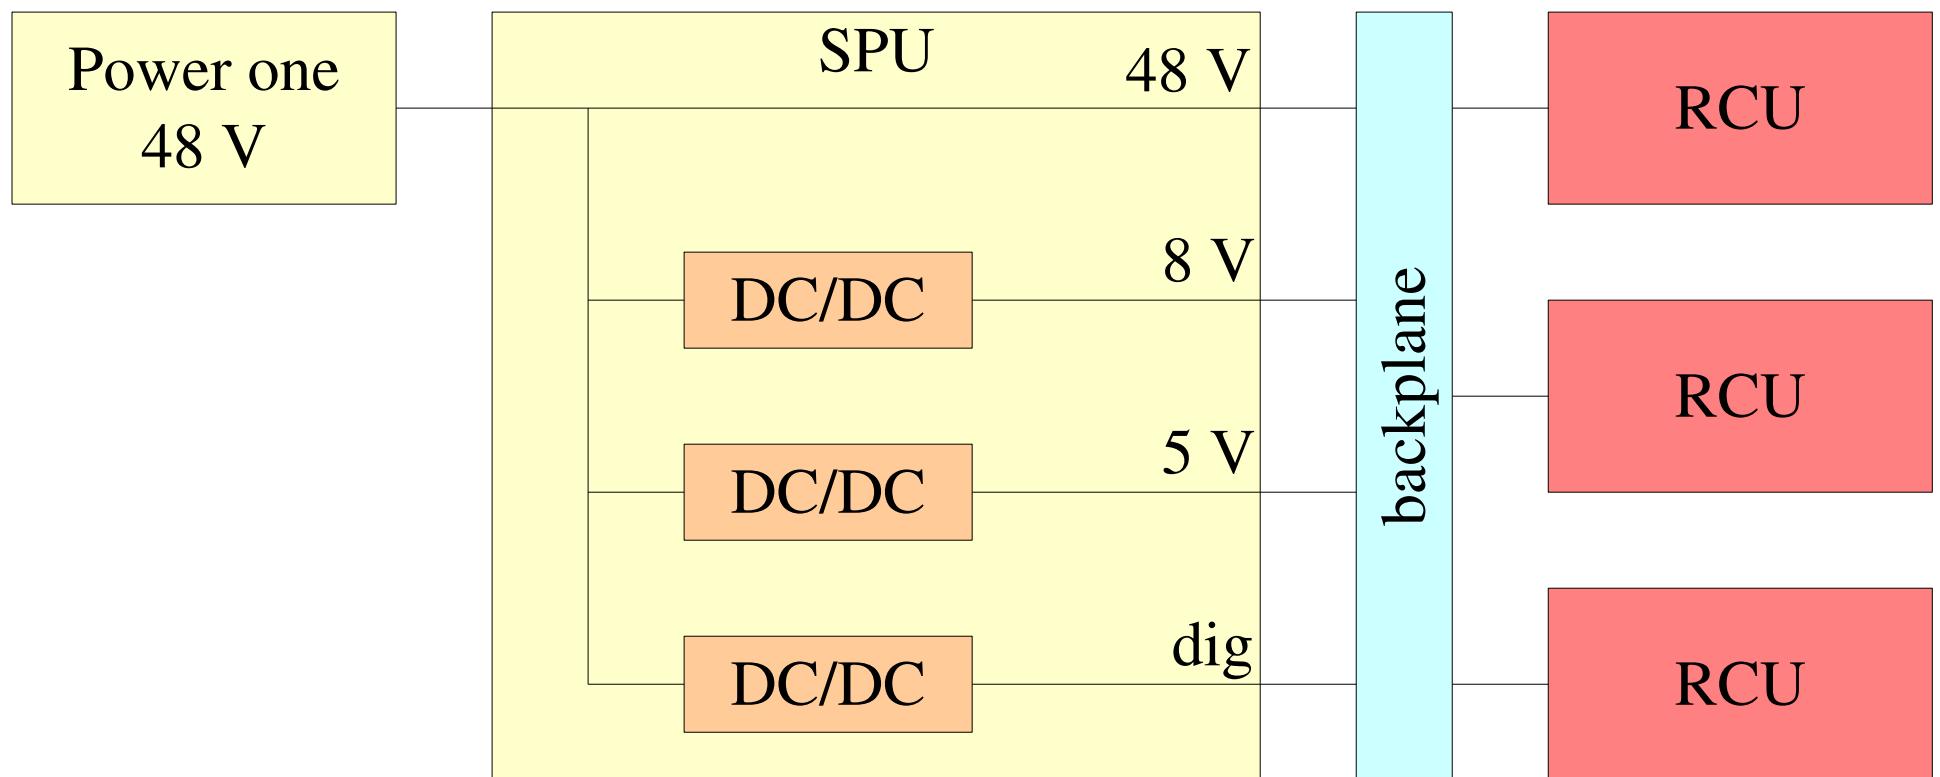

crosscorrelation amplitude (left) and phase (right)

Power supply has serious impact

Station power distribution

ASTRON

Measurement description

Only crosstalk within subrack -> Power One ok!

Goal: find the cause of the correlation artefacts

DE604C

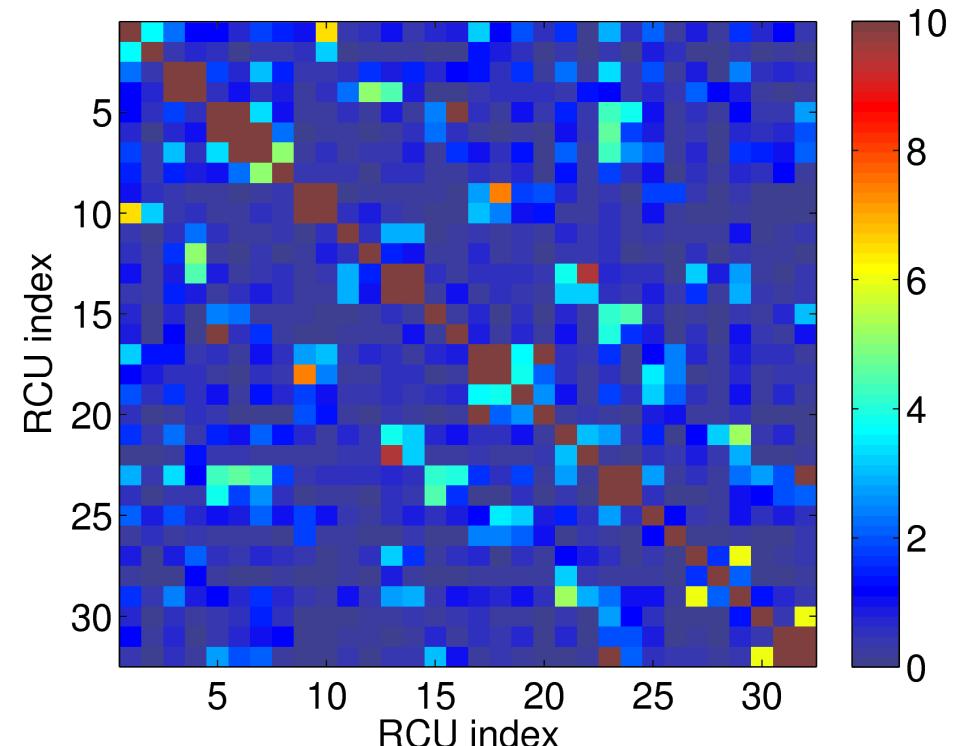

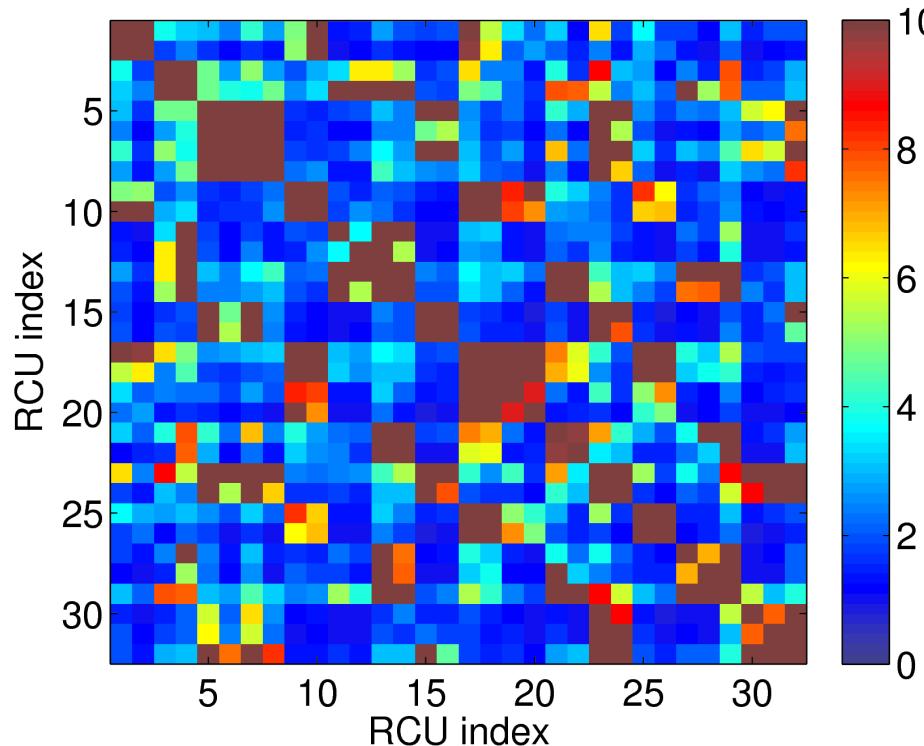

- single subrack in lab
- loads on all inputs
- crosstalk measurements do reproduce
- frequency sweeps with 64 s integration per subband

Test 1: short circuited 48 V SPU output

ASTRON

average absolute value (l) and absolute average value (r)

Conclusion: 48 V SPU output clean

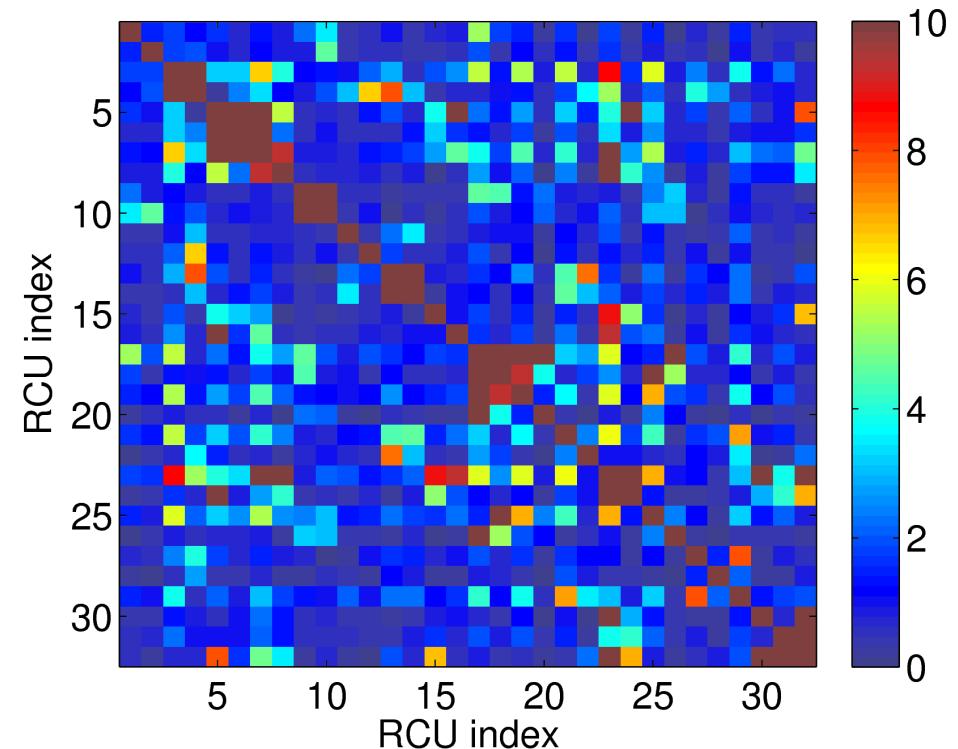

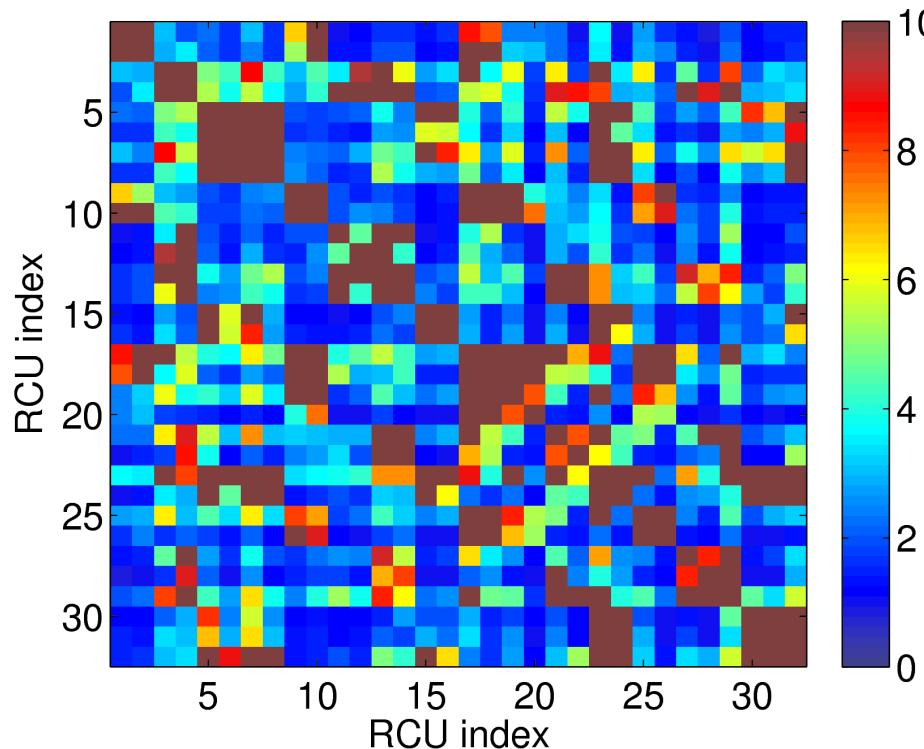

Test 2: short circuited 48 V RCU input

ASTRON

scan over subbands 300 – 450 (112.5 – 141.8 MHz)

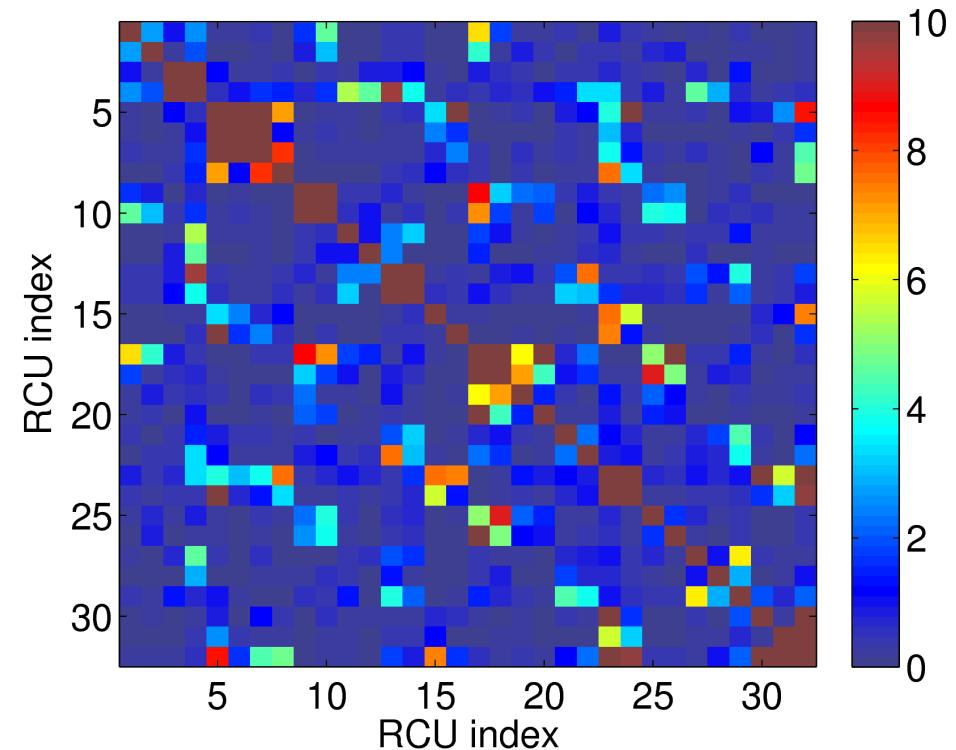

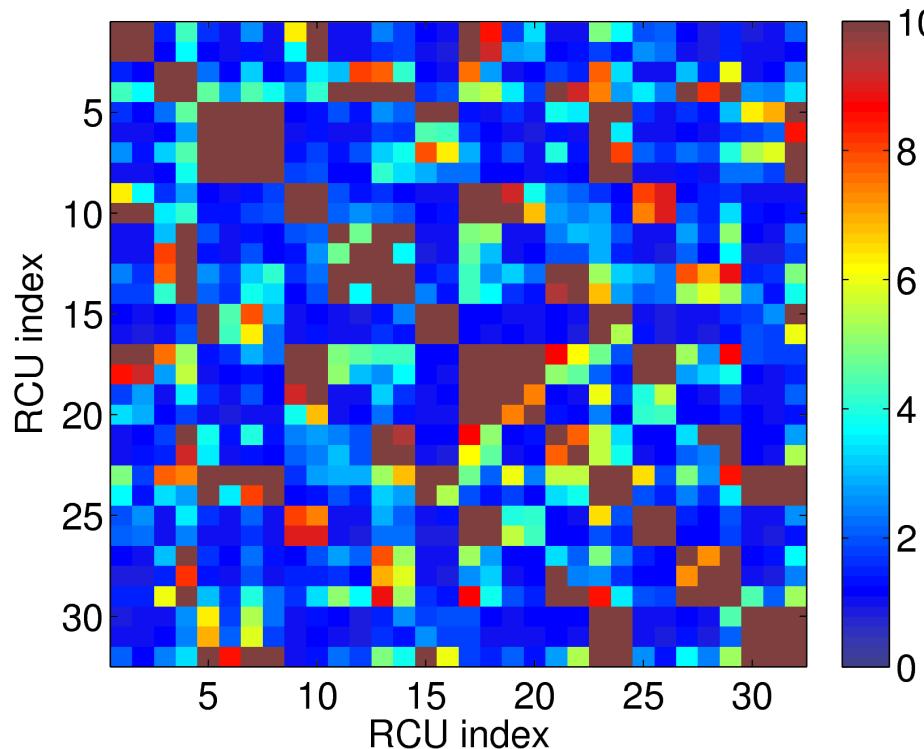

Conclusion: signal induced between SPU and RCU

Test 3: 8 V SPU out from battery pack

ASTRON

Conclusion: DC/DC couplers 8 V supply generate dirty signal that couples to 48 V lines on backplane

Three problems

1. DC/DC for 8 V produces dirty signal
2. crosstalk on backplane from 8 V to 48 V power lines
3. DC-filter on 48 V RCU input insufficient

Solutions

- new backplane series: not a real solution:
 - old ones still there
 - dirty power lines still there
- replace SPUs of core stations
